This bitfield reflects the number of words in the message that have already been pushed into the IN FIFO.

NBW increments (+1) when a write access is performed to the HASH\_DIN register while DINNE = 1.

It goes to 0000 when the INIT bit is written to 1 or when a digest calculation starts (DCAL written to 1 or DMA end of transfer).

" If the DMA is not used:

0000 and DINNE=0: no word has been pushed into the DIN buffer (the buffer is empty, both the HASH\_DIN register and the IN FIFO are empty)

0000 and DINNE=1: 1 word has been pushed into the DIN buffer (The HASH\_DIN register contains 1 word, the IN FIFO is empty)

0001: 2 words have been pushed into the DIN buffer (the HASH\_DIN register and the IN FIFO contain 1 word each)

...

1111: 16 words have been pushed into the DIN buffer

" If the DMA is used, NBW is the exact number of words that have been pushed into the IN FIFO.

Bit 18 and bit 7 **ALGO[1:0]**: Algorithm selection

These bits select the SHA-1, SHA-224, SHA256 or the MD5 algorithm:

00: SHA-1 algorithm selected

01: MD5 algorithm selected

10: SHA224 algorithm selected

11: SHA256 algorithm selected

*Note: This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.*

Bit 6 **MODE**: Mode selection

This bit selects the HASH or HMAC mode for the selected algorithm:

0: Hash mode selected

1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.

*Note: This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.*

Bits 5:4 **DATATYPE**: Data type selection

Defines the format of the data entered into the HASH\_DIN register:

00: 32-bit data. The data written into HASH\_DIN are directly used by the HASH processing, without reordering.

01: 16-bit data, or half-word. The data written into HASH\_DIN are considered as 2 half-words, and are swapped before being used by the HASH processing.

10: 8-bit data, or bytes. The data written into HASH\_DIN are considered as 4 bytes, and are swapped before being used by the HASH processing.

11: bit data, or bit-string. The data written into HASH\_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE**: DMA enable

0: DMA transfers disabled

1: DMA transfers enabled. A DMA request is sent as soon as the HASH core is ready to receive data.

*Note: 1: This bit is cleared by hardware when the DMA asserts the DMA terminal count signal (while transferring the last data of the message). This bit is not cleared when the INIT bit is written to 1.*

*2: If this bit is written to 0 while a DMA transfer has already been requested to the DMA, DMAE is cleared but the current transfer is not aborted. Instead, the DMA interface remains internally enabled until the transfer is complete or INIT is written to 1.*

Bit 2 **INIT**: Initialize message digest calculation

Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.

Writing this bit to 0 has no effect.

Reading this bit always return 0.

Bits 1:0 Reserved, must be kept cleared.

### 25.4.3 HASH data input register (HASH\_DIN)

Address offset: 0x04

Reset value: 0x0000 0000

HASH\_DIN is the data input register. It is 32-bit wide. It is used to enter the message by blocks of 512 bits. When the HASH\_DIN register is written to, the value presented on the AHB databus is 'pushed' into the HASH core and the register takes the new value presented on the AHB databus. The DATATYPE bits must previously have been configured in the HASH\_CR register to get a correct message representation.

When a block of 16 words has been written to the HASH\_DIN register, an intermediate digest calculation is launched:

- by writing new data into the HASH\_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation)
- automatically if the DMA is used

When the last block has been written to the HASH\_DIN register, the final digest calculation (including padding) is launched:

- by writing the DCAL bit to 1 in the HASH\_STR register (final digest calculation)
- automatically if the DMA is used and MDMAT bit is set to '0'.

When a digest calculation (intermediate or final) is in progress, any new write access to the HASH\_DIN register is extended (by wait-state insertion on the AHB bus) until the HASH calculation completes.

When the HASH\_DIN register is read, the last word written in this location is accessed (zero after reset).

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAIN |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAIN |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATAIN**: Data input

Read = returns the current register content.

Write = the current register content is pushed into the IN FIFO, and the register takes the new value presented on the AHB databus.

## 25.4.4 HASH start register (HASH\_STR)

Address offset: 0x08

Reset value: 0x0000 0000

The HASH\_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written into the HASH\_DIN register)
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1

|          |    |    |    |    |    |    |      |          |    |    |    |      |    |    |    |
|----------|----|----|----|----|----|----|------|----------|----|----|----|------|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24   | 23       | 22 | 21 | 20 | 19   | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |      |          |    |    |    |      |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8    | 7        | 6  | 5  | 4  | 3    | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    | DCAL | Reserved |    |    |    | NBLW |    |    |    |
|          |    |    |    |    |    |    | w    |          |    |    |    | rw   | rw | rw | rw |

Bits 31:9 Reserved, forced by hardware to 0.

Bit 8 **DCAL**: Digest calculation

Writing this bit to 1 starts the message padding, using the previously written value of NBLW, and starts the calculation of the final message digest with all data words written to the IN FIFO since the INIT bit was last written to 1.

Reading this bit returns 0.

Note

Bits 7:5 Reserved, forced by hardware to 0.

Bits 4:0 **NBLW**: Number of valid bits in the last word of the message in the bit string organization of hash processor

When these bits are written and DCAL is at '0', they take the value on the AHB databus:

0x00: All 32 bits of the last data written in the bit string organization of hash processor (after data swapping) are valid.

0x01: Only bit [31] of the last data written in the bit string organization of hash processor (after data swapping) are valid

0x02: Only bits [31:30] of the last data written in the bit string organization of hash processor (after data swapping) are valid

0x03: Only bits [31:29] of the last data written in the bit string organization of hash processor (after data swapping) are valid

...

0x1F: Only bits [0] of the last data written in the bit string organization of hash processor (after data swapping) are valid

When these bits are written and DCAL is at '1', the bitfield is not changed.

Reading them returns the last value written to NBLW.

*Note: These bits must be configured before setting the DCAL bit, else they are not taken into account. Especially, it is not possible to configure NBLW and set DCAL at the same time.*

## 25.4.5 HASH digest registers (HASH\_HR0..4/5/6/7)

Address offset: 0x0C to 0x1C (STM32F415/417xx), plus 0x310 to 0x32C (STM32F43xxx)

Reset value: 0x0000 0000

These registers contain the message digest result named as:

1. H0, H1, H2, H3 and H4, respectively, in the SHA1 algorithm description  
Note that in this case, the HASH\_H5 to HASH\_H7 register is not used, and is read as zero.
2. A, B, C and D, respectively, in the MD5 algorithm description  
Note that in this case, the HASH\_H4 to HASH\_H7 register is not used, and is read as zero.
3. H0 to H6, respectively, in the SHA224 algorithm description,  
Note that in this case, the HASH\_H7 register is not used, and is read as zero.
4. H0 to H7, respectively, in the SHA256 algorithm description,

If a read access to one of these registers occurs while the HASH core is calculating an intermediate digest or a final message digest (that is when the DCAL bit has been written to 1), then the read is stalled until the completion of the HASH calculation.

*Note: H0, H1, H2, H3 and H4 mapping are duplicated in two region.*

### HASH\_HR0

Address offset: 0x0C and 0x310

|    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| Reserved |    |    |    |    |    |    |    |    |    |    |    | BUSY | DMAS | DCIS  | DINIS |
|          |    |    |    |    |    |    |    |    |    |    |    | r    | r    | rc_w0 | rc_w0 |

Bits 31:4 Reserved, forced by hardware to 0.

Bit 3 **BUSY**: Busy bit

- 0: No block is currently being processed
- 1: The hash core is processing a block of data

Bit 2 **DMAS**: DMA Status

This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE=0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

- 0: DMA interface is disabled (DMAE=0) and no transfer is ongoing
- 1: DMA interface is enabled (DMAE=1) or a transfer is ongoing

Bit 1 **DCIS**: Digest calculation completion interrupt status

This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by writing the INIT bit to 1 in the HASH\_CR register.

- 0: No digest available in the HASH\_Hx registers
- 1: Digest calculation complete, a digest is available in the HASH\_Hx registers. An interrupt is generated if the DCIE bit is set in the HASH\_IMR register.

Bit 0 **DINIS**: Data input interrupt status

This bit is set by hardware when the input buffer is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH\_DIN register.

- 0: Less than 16 locations are free in the input buffer
- 1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH\_IMR register.

## 25.4.8 HASH context swap registers (HASH\_CSRx)

Address offset: 0x0F8 to 0x1C0

- For HASH\_CSR0 register: Reset value is 0x0000 0002.
- For others registers: Reset value is 0x0000 0000 , except for STM32F43xxx devices where the HASH\_CSR2 register reset value is 0x2000 0000

Additional registers are available from 0x1C1 to 0x1CC on STM32F43xxx:

- Reset value: 0x0000 0000.

These registers contain the complete internal register states of the hash processor, and are useful when a context swap has to be done because a high-priority task has to use the hash processor while it is already in use by another task.

When such an event occurs, the HASH\_CSRx registers have to be read and the read values have to be saved somewhere in the system memory space. Then the hash processor can be used by the preemptive task, and when hash computation is finished, the saved context can be read from memory and written back into these HASH\_CSRx registers.

### HASH\_CSRx

Address offset: 0x0F8 to 0x1C0 on STM32F415/417xx

Address offset: 0x0F8 to 0x1CC on STM32F43xxx

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

## 26 Real-time clock (RTC)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 26.1 Introduction

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar, two programmable alarm interrupts, and a periodic programmable wake-up flag with interrupt capability. The RTC also includes an automatic wake-up unit to manage low-power modes.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After backup domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).

## 26.2 RTC main features

The RTC unit main features are the following (see [Figure 237: RTC block diagram](#)):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Two programmable alarms with interrupt function. The alarms can be triggered by any combination of the calendar fields.
- Automatic wake-up unit generating a periodic flag that triggers an automatic wake-up interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wake-up interrupt
  - Timestamp
  - Tamper detection
- Digital calibration circuit (periodic counter correction)
  - 5 ppm accuracy
  - 0.95 ppm accuracy, obtained in a calibration window of several seconds
- Timestamp function for event saving (1 event)
- Tamper detection:
  - 2 tamper events with configurable filter and internal pull-up.
- 20 backup registers (80 bytes). The backup registers are reset when a tamper detection event occurs.
- Alternate function output (RTC\_OUT) which selects one of the following two outputs:
  - RTC\_CALIB: 512 Hz or 1 Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC\_CR register. It is routed to the device RTC\_AF1 function.
  - RTC\_ALARM (Alarm A, Alarm B or wake-up). This output is selected by configuring the OSEL[1:0] bits in the RTC\_CR register. It is routed to the device RTC\_AF1 function.
- RTC alternate function inputs:
  - RTC\_TS: timestamp event detection. It is routed to the device RTC\_AF1 and RTC\_AF2 functions.
  - RTC\_TAMP1: TAMPER1 event detection. It is routed to the device RTC\_AF1 and RTC\_AF2 functions.
  - RTC\_TAMP2: TAMPER2 event detection.
  - RTC\_REFIN: reference clock input (usually the mains, 50 or 60 Hz).

Refer to [Section 8.3.15: Selection of RTC\\_AF1 and RTC\\_AF2 alternate functions](#).

Figure 237. RTC block diagram

1. On STM32F4xx devices, the RTC\_AF1 and RTC\_AF2 alternate functions are connected to PC13 and PI8, respectively.

## 26.3 RTC functional description

### 26.3.1 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to [Section 7: Reset and clock control for STM32F405xx/07xx and STM32F415xx/17xx\(RCC\)](#) and [Section 6: Reset and clock control for STM32F42xxx and STM32F43xxx \(RCC\)](#).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see [Figure 237: RTC block diagram](#)):

- A 7-bit asynchronous prescaler configured through the PREDIV\_A bits of the RTC\_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV\_S bits of the RTC\_PRER register.

*Note:* When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck\_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is  $2^{22}$ .

This corresponds to a maximum input frequency of around 4 MHz.

$f_{ck\_apre}$  is given by the following formula:

$$f_{CK\_APRE} = \frac{f_{RTCCLK}}{PREDIV\_A + 1}$$

The ck\_apre clock is used to clock the binary RTC\_SSR subseconds downcounter. When it reaches 0, RTC\_SSR is reloaded with the content of PREDIV\_S.

$f_{ck\_spre}$  is given by the following formula:

$$f_{CK\_SPRE} = \frac{f_{RTCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)}$$

The ck\_spre clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see [Section 26.3.4: Periodic auto-wakeup](#) for details).

### 26.3.2 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK1 (APB1 clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC\_SSR for the subseconds
- RTC\_TR for the time
- RTC\_DR for the date

Every two RTCCLK periods, the current calendar value is copied into the shadow registers, and the RSF bit of RTC\_ISR register is set (see [Section 26.6.4](#)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 2 RTCCLK periods.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC\_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC\_SSR, RTC\_TR or RTC\_DR registers in BYPSHAD=0 mode, the frequency of the APB clock ( $f_{APB}$ ) must be at least 7 times the frequency of the RTC clock ( $f_{RTCCLK}$ ).

The shadow registers are reset by system reset.

### 26.3.3 Programmable alarms

The RTC unit provides two programmable alarms, Alarm A and Alarm B.

The programmable alarm functions are enabled through the ALRAIE and ALRBIE bits in the RTC\_CR register. The ALRAF and ALRBF flags are set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC\_ALRMASR/RTC\_ALRMAR and RTC\_ALRMBSSR/RTC\_ALRMBR, respectively. Each calendar field can be independently selected through the MSKx bits of the RTC\_ALRMAR and RTC\_ALRMBR registers, and through the MASKSSx bits of the RTC\_ALRMASR and RTC\_ALRMBSSR registers. The alarm interrupts are enabled through the ALRAIE and ALRBIE bits in the RTC\_CR register.

Alarm A and Alarm B (if enabled by bits OSEL[1:0] in RTC\_CR register) can be routed to the RTC\_ALARM output. RTC\_ALARM polarity can be configured through bit POL in the RTC\_CR register.

**Caution:** If the seconds field is selected (MSK0 bit reset in RTC\_ALRMAR or RTC\_ALRMBR), the synchronous prescaler division factor set in the RTC\_PRER register must be at least 3 to ensure correct behavior.

### 26.3.4 Periodic auto-wakeup

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC\_CR register.

The wake-up timer clock input can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.  
When RTCCLK is LSE(32.768kHz), this allows configuring the wake-up interrupt period from 122  $\mu$ s to 32 s, with a resolution down to 61  $\mu$ s.
- ck\_spre (usually 1 Hz internal clock)  
When ck\_spre frequency is 1Hz, this allows achieving a wake-up time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1s to 18 hours when WUCKSEL[2:1] = 10
  - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case 2<sup>16</sup> is added to the 16-bit counter current value. When the initialization sequence is complete (see [Programming the wake-up timer on page 808](#)), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC\_ISR register, and the wake-up counter is automatically reloaded with its reload value (RTC\_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC\_CR2 register, it can exit the device from low-power modes.

The periodic wake-up flag can be routed to the RTC\_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC\_CR register. RTC\_ALARM polarity can be configured through the POL bit in the RTC\_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wake-up timer.

### 26.3.5 RTC initialization and configuration

#### RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

#### RTC register write protection

After system reset, the RTC registers are protected against parasitic write access with the DBP bit of the PWR power control register (PWR\_CR). The DBP bit must be set to enable RTC registers write access.

After backup domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC\_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC\_ISR[13:8], RTC\_TAFCR, and RTC\_BKPxR.

1. Write '0xCA' into the RTC\_WPR register.
2. Write '0x53' into the RTC\_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

### Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC\_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC\_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes from 1 to 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program first the synchronous prescaler factor in RTC\_PRER register, and then program the asynchronous prescaler factor. Even if only one of the two fields needs to be changed, 2 separate write accesses must be performed to the RTC\_PRER register.
4. Load the initial time and date values in the shadow registers (RTC\_TR and RTC\_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC\_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

**Note:** *After a system reset, the application can read the INITS flag in the RTC\_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its backup domain reset default value (0x00). To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC\_ISR register.*

### Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC\_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

### Programming the alarm

A similar procedure must be followed to program or update the programmable alarm (Alarm A or Alarm B):

1. Clear ALRAE or ALRBIE in RTC\_CR to disable Alarm A or Alarm B.
2. Poll ALRAWF or ALRBWF in RTC\_ISR until it is set to make sure the access to alarm registers is allowed. This takes 1 to 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the Alarm A or Alarm B registers (RTC\_ALRMASR/RTC\_ALRMAR or RTC\_ALRMBSSR/RTC\_ALRMBR).
4. Set ALRAE or ALRBIE in the RTC\_CR register to enable Alarm A or Alarm B again.

**Note:** *Each change of the RTC\_CR register is taken into account after 1 to 2 RTCCLK clock cycles due to clock synchronization.*

### Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC\_WUTR):

1. Clear WUTE in RTC\_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC\_ISR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes 1 to 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wake-up auto-reload value WUT[15:0], and the wake-up clock selection (WUCKSEL[2:0] bits in RTC\_CR). Set WUTE in RTC\_CR to enable the timer again. The wake-up timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCLK clocks cycles after WUTE is cleared, due to clock synchronization.

### 26.3.6 Reading the calendar

#### When BYPSHAD control bit is cleared in the RTC\_CR register

To read the RTC calendar registers (RTC\_SSR, RTC\_TR and RTC\_DR) properly, the APB1 clock frequency ( $f_{PCLK1}$ ) must be equal to or greater than seven times the  $f_{RTCCLK}$  RTC clock frequency. This ensures a secure behavior of the synchronization mechanism.

If the APB1 clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB1 clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC\_ISR register each time the calendar registers are copied into the RTC\_SSR, RTC\_TR and RTC\_DR shadow registers. The copy is performed every two RTCCLK cycles. To ensure consistency between the 3 values, reading either RTC\_SSR or RTC\_TR locks the values in the higher-order calendar shadow registers until RTC\_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCLK periods: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

**Note:** *After a system reset, the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers. Indeed, a system reset resets the shadow registers to their default values.*

*After an initialization (refer to [Calendar initialization and configuration on page 807](#)): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.*

*After synchronization (refer to [Section 26.3.8: RTC synchronization](#)): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.*

### When the BYPSHAD control bit is set in the RTC\_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

*Note:* While BYPSHAD=1, instructions which read the calendar registers require one extra APB cycle to complete.

## 26.3.7 Resetting the RTC

The calendar shadow registers (RTC\_SSR, RTC\_TR and RTC\_DR) and some bits of the RTC status register (RTC\_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC\_CR), the prescaler register (RTC\_PRER), the RTC calibration registers (RTC\_CALIBR or RTC\_CALR), the RTC shift register (RTC\_SHIFTR), the RTC timestamp registers (RTC\_TSSSR, RTC\_TSTR and RTC\_TSDR), the RTC tamper and alternate function configuration register (RTC\_TAFCR), the RTC backup registers (RTC\_BKPxR), the wake-up timer register (RTC\_WUTR), the Alarm A and Alarm B registers (RTC\_ALRMASR/RTC\_ALMAR and RTC\_ALRMBSSR/RTC\_ALMRB).

In addition, when the RTC is clocked by the LSE, it goes on running under system reset if the reset source is different from a backup domain reset one. Refer to section *RTC clock* of the *Reset and clock controller* for details about the list of the RTC clock sources that are not affected by system reset.

When a backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

## 26.3.8 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC\_SSR or RTC\_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC\_SHIFTR.

RTC\_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of  $1 / (\text{PREDIV\_S} + 1)$  seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV\_S[14:0]). The maximum resolution allowed (30.52  $\mu$ s with a 32768 Hz clock) is obtained with PREDIV\_S set to 0x7FFF.

However, increasing PREDIV\_S means that PREDIV\_A must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC\_SHIFTR). Writing to RTC\_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of  $1 / (\text{PREDIV\_S} + 1)$  seconds. The shift operation consists of adding the SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this delays the clock. If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this advances the clock.

**Caution:** Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow occurs.

As soon as a shift operation is initiated by a write to the RTC\_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

**Caution:** This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC\_SHIFTR when REFCKON=1.

### 26.3.9 RTC reference clock detection

The RTC calendar update can be synchronized to a reference clock RTC\_REFIN, usually the mains (50 or 60 Hz). The RTC\_REFIN reference clock should have a higher precision than the 32.768 kHz LSE clock. When the RTC\_REFIN detection is enabled (REFCKON bit of RTC\_CR set to 1), the calendar is still clocked by the LSE, and RTC\_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest reference clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck\_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck\_apre periods when detecting the first reference clock edge. A smaller window of 3 ck\_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the synchronous prescaler which outputs the ck\_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck\_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck\_apre period detection window centered on the ck\_spre edge.

When the reference clock detection is enabled, PREDIV\_A and PREDIV\_S must be set to their default values:

- PREDIV\_A = 0x007F
- PREDIV\_S = 0x00FF

**Note:** *The reference clock detection is not available in Standby mode.*

**Caution:** The reference clock detection feature cannot be used in conjunction with the coarse digital calibration: RTC\_CALIBR must be kept at 0x0000 0000 when REFCKON=1.

### 26.3.10 RTC coarse digital calibration

Two digital calibration methods are available: coarse and smooth calibration. To perform coarse calibration refer to [Section 26.6.7: RTC calibration register \(RTC\\_CALIBR\)](#).

The two calibration methods are not intended to be used together, the application must select one of the two methods. Coarse calibration is provided for compatibility reasons. To perform smooth calibration refer to [Section 26.3.11: RTC smooth digital calibration](#) and the [Section 26.6.16: RTC calibration register \(RTC\\_CALR\)](#)

The coarse digital calibration can be used to compensate crystal inaccuracy by adding (positive calibration) or masking (negative calibration) clock cycles at the output of the asynchronous prescaler (ck\_apre).

Positive and negative calibration are selected by setting the DCS bit in RTC\_CALIBR register to '0' and '1', respectively.

When positive calibration is enabled (DCS = '0'), 2 ck\_apre cycles are added every minute (around 15360 ck\_apre cycles) for 2xDC minutes. This causes the calendar to be updated sooner, thereby adjusting the effective RTC frequency to be a bit higher.

When negative calibration is enabled (DCS = '1'), 1 ck\_apre cycle is removed every minute (around 15360 ck\_apre cycles) for 2xDC minutes. This causes the calendar to be updated later, thereby adjusting the effective RTC frequency to be a bit lower.

DC is configured through bits DC[4:0] of RTC\_CALIBR register. This number ranges from 0 to 31 corresponding to a time interval (2xDC) ranging from 0 to 62.

The coarse digital calibration can be configured only in initialization mode, and starts when the INIT bit is cleared. The full calibration cycle lasts 64 minutes. The first 2xDC minutes of the 64 -minute cycle are modified as just described.

Negative calibration can be performed with a resolution of about 2 ppm while positive calibration can be performed with a resolution of about 4 ppm. The maximum calibration ranges from -63 ppm to 126 ppm.

The calibration can be performed either on the LSE or on the HSE clock.

**Caution:** Digital calibration may not work correctly if PREDIV\_A < 6.

#### Case of RTCCLK=32.768 kHz and PREDIV\_A+1=128

The following description assumes that ck\_apre frequency is 256 Hz obtained with an LSE clock nominal frequency of 32.768 kHz, and PREDIV\_A set to 127 (default value).

The ck\_spre clock frequency is only modified during the first 2xDC minutes of the 64-minute cycle. For example, when DC equals 1, only the first 2 minutes are modified. This means that the first 2xDC minutes of each 64-minute cycle have, once per minute, one second

either shortened by 256 or lengthened by 128 RTCCLK cycles, given that each ck\_apre cycle represents 128 RTCCLK cycles (with PREDIV\_A+1=128).

Therefore each calibration step has the effect of adding 512 or subtracting 256 oscillator cycles for every 125829120 RTCCLK cycles (64min x 60 s/min x 32768 cycles/s). This is equivalent to +4.069 ppm or -2.035 ppm per calibration step. As a result, the calibration resolution is +10.5 or -5.27 seconds per month, and the total calibration ranges from +5.45 to -2.72 minutes per month.

In order to measure the clock deviation, a 512 Hz clock is output for calibration. Refer to [Section 26.3.14: Calibration clock output](#).

### 26.3.11 RTC smooth digital calibration

RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about  $2^{20}$  RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. [This cycle is maintained by a 20-bit counter, cal\\_cnt\[19:0\], clocked by RTCCLK.](#)

The smooth calibration register (RTC\_CALR) specifies the number of RTCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting CALM[2] to 1 causes four additional cycles to be masked
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

*Note:* CALM[8:0] (RTC\_CALRx) specifies the number of RTCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to '1' causes exactly one pulse to be masked during the 32-second cycle [at the moment when cal\\_cnt\[19:0\] is 0x80000](#); CALM[1]=1 causes two other cycles to be masked [\(when cal\\_cnt is 0x40000 and 0xC0000\)](#); CALM[2]=1 causes four other cycles to be masked [\(cal\\_cnt = 0x20000/0x60000/0xA0000/ 0xE0000\)](#); and so on up to CALM[8]=1 which causes 256 clocks to be masked [\(cal\\_cnt = 0xXX800\)](#).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to '1' effectively inserts an extra RTCCLK pulse every  $2^{11}$  RTCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (FCAL) given the input frequency (FRTCCLK) is as follows:

$$F_{\text{CAL}} = F_{\text{RTCCLK}} \times [1 + (\text{CALP} \times 512 - \text{CALM}) / (2^{20} + \text{CALM} - \text{CALP} \times 512)]$$

#### Calibration when PREDIV\_A<3

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV\_A bits in RTC\_PRER register) is less than 3. If CALP was already set to 1 and PREDIV\_A bits are

set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV\_A less than 3, the synchronous prescaler value (PREDIV\_S) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV\_A equals 1 (division factor of 2), PREDIV\_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV\_A equals 0, PREDIV\_S should be set to 32759 rather than 32767 (8 less).

If PREDIV\_S is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

$$F_{\text{CAL}} = F_{\text{RTCCLK}} \times [1 + (256 - \text{CALM}) / (2^{20} + \text{CALM} - 256)]$$

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

### Verifying the RTC calibration

RTC precision is performed by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.  
Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).
- CALW16 bit of the RTC\_CALR register can be set to 1 to force a 16- second calibration cycle period.  
In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.
- CALW8 bit of the RTC\_CALR register can be set to 1 to force a 8- second calibration cycle period.  
In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

### Re-calibration on-the-fly

The calibration register (RTC\_CALR) can be updated on-the-fly while RTC\_ISR/INITF=0, by using the follow process:

1. Poll the RTC\_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC\_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck\_apre cycles after the write operation to RTC\_CALR, the new calibration settings take effect.

### 26.3.12 Timestamp function

Timestamp is enabled by setting the TSE bit of RTC\_CR register to 1.

The calendar is saved in the timestamp registers (RTC\_TSSSR, RTC\_TSTR, RTC\_TSDR) when a timestamp event is detected on the pin to which the TIMESTAMP alternate function is mapped. When a timestamp event occurs, the timestamp flag bit (TSF) in RTC\_ISR register is set.

By setting the TSIE bit in the RTC\_CR register, an interrupt is generated when a timestamp event occurs.

If a new timestamp event is detected while the timestamp flag (TSF) is already set, the timestamp overflow flag (TSOVF) flag is set and the timestamp registers (RTC\_TSTR and RTC\_TSDR) maintain the results of the previous event.

**Note:** *TSF is set 2 ck\_apre cycles after the timestamp event occurs due to synchronization process.*

*There is no delay in the setting of TSOVF. This means that if two timestamp events are close together, TSOVF can be seen as '1' while TSF is still '0'. As a consequence, it is recommended to poll TSOVF only after TSF has been set.*

**Caution:** If a timestamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a timestamp event occurring at the same moment, the application must not write '0' into TSF bit unless it has already read it to '1'.

Optionally, a tamper event can cause a timestamp to be recorded. See the description of the TAMPTS control bit in [Section 26.6.17: RTC tamper and alternate function configuration register \(RTC\\_TAFCR\)](#). If the timestamp event is on the same pin as a tamper event configured in filtered mode (TAMPFLT set to a non-zero value), the timestamp on tamper detection event mode must be selected by setting TAMPTS='1' in RTC\_TAFCR register.

#### TIMESTAMP alternate function

The TIMESTAMP alternate function (RTC\_TS) can be mapped either to RTC\_AF1 or to RTC\_AF2 depending on the value of the TSINSEL bit in the RTC\_TAFCR register (see [Section 26.6.17: RTC tamper and alternate function configuration register \(RTC\\_TAFCR\)](#)). Mapping the timestamp event on RTC\_AF2 is not allowed if RTC\_AF1 is used as TAMPER in filtered mode (TAMPFLT set to a non-zero value).

### 26.3.13 Tamper detection

Two tamper detection inputs are available. They can be configured either for edge detection, or for level detection with filtering.

#### RTC backup registers

The backup registers (RTC\_BKPxR) are twenty 32-bit registers for storing 80 bytes of user application data. They are implemented in the backup domain that remains powered-on by

$V_{BAT}$  when the  $V_{DD}$  power is switched off. They are not reset by system reset or when the device wakes up from Standby mode. They are reset by a backup domain reset

The backup registers are reset when a tamper detection event occurs (see [Section 26.6.20: RTC backup registers \(RTC\\_BKPxR\)](#) and [Tamper detection initialization on page 815](#)).

### Tamper detection initialization

Each tamper detection input is associated with the TAMP1F/TAMP2F flags in the RTC\_ISR2 register. Each input can be enabled by setting the corresponding TAMP1E/TAMP2E bits to 1 in the RTC\_TAFCR register.

A tamper detection event resets all backup registers (RTC\_BKPxR).

By setting the TAMPIE bit in the RTC\_TAFCR register, an interrupt is generated when a tamper detection event occurs.

### Timestamp on tamper event

With TAMPTS set to '1', any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit are set in RTC\_ISR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register (TAMP1F, TAMP2F) is set at the same time that TSF or TSOVF is set.

### Edge detection on tamper inputs

If the TAMPFLT bits are "00", the TAMPER pins generate tamper detection events (RTC\_TAMP[2:1]) when either a rising edge is observed or an falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the TAMPER inputs are deactivated when edge detection is selected.

**Caution:** To avoid losing tamper detection events, the signal used for edge detection is logically ANDed with TAMPxE in order to detect a tamper detection event in case it occurs before the TAMPERx pin is enabled.

- When TAMPxTRG = 0: if the TAMPERx alternate function is already high before tamper detection is enabled (TAMPxE bit set to 1), a tamper event is detected as soon as TAMPERx is enabled, even if there was no rising edge on TAMPERx after TAMPxE was set.
- When TAMPxTRG = 1: if the TAMPERx alternate function is already low before tamper detection is enabled, a tamper event is detected as soon as TAMPERx is enabled (even if there was no falling edge on TAMPERx after TAMPxE was set).

After a tamper event has been detected and cleared, the TAMPERx alternate function should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC\_BKPxR). This prevents the application from writing to the backup registers while the TAMPERx value still indicates a tamper detection. This is equivalent to a level detection on the TAMPERx alternate function.

**Note:** *Tamper detection is still active when  $V_{DD}$  power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the TAMPER alternate function is mapped should be externally tied to the correct level.*

### Level detection with filtering on tamper inputs

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive

samples are observed at the level designated by the TAMPxTRG bits (TAMP1TRG/TAMP2TRG).

The TAMPER inputs are pre-charged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the tamper inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

*Note:* Refer to the datasheets for the electrical characteristics of the pull-up resistors.

### TAMPER alternate function detection

The TAMPER1 alternate function (RTC\_TAMP1) can be mapped either to RTC\_AF1(PC13) or RTC\_AF2 (PI8) depending on the value of TAMP1INSEL bit in RTC\_TAFCR register (see [Section 26.6.17: RTC tamper and alternate function configuration register \(RTC\\_TAFCR\)](#)). TAMPE bit must be cleared when TAMP1INSEL is modified to avoid unwanted setting of TAMPF.

The TAMPER 2 alternate function corresponds to RTC\_TAMP2 pin.

## 26.3.14 Calibration clock output

When the COE bit is set to 1 in the RTC\_CR register, a reference clock is provided on the RTC\_CALIB device output. If the COSEL bit in the RTC\_CR register is reset and PREDIV\_A = 0x7F, the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/64$ . This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz.

The RTC\_CALIB output is not impacted by the calibration value programmed in RTC\_CALIBR register. The RTC\_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

If COSEL is set and (PREDIV\_S+1) is a non-zero multiple of 256 (i.e: PREDIV\_S[7:0] = 0xFF), the RTC\_CALIB frequency is  $f_{\text{RTCCLK}}/(256 * (\text{PREDIV\_A}+1))$ . This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV\_A = 0x7F, PREDIV\_S = 0xFF), with an RTCCLK frequency at 32.768 kHz. The 1 Hz output is affected when a shift operation is on going and may toggle during the shift operation (SHPF=1).

### Calibration alternate function output

When the COE bit in the RTC\_CR register is set to 1, the calibration alternate function (RTC\_CALIB) is enabled on RTC\_AF1.

*Note:* When RTC\_CALIB or RTC\_ALARM is selected, RTC\_AF1 is automatically configured in output alternate function.

## 26.3.15 Alarm output

Three functions can be selected on Alarm output: ALRAF, ALRBF and WUTF. These functions reflect the contents of the corresponding flags in the RTC\_ISR register.

The OSEL[1:0] control bits in the RTC\_CR register are used to activate the alarm alternate function output (RTC\_ALARM) in RTC\_AF1, and to select the function which is output on RTC\_ALARM.

The polarity of the output is determined by the POL control bit in RTC\_CR so that the opposite of the selected flag bit is output when POL is set to 1.

### Alarm alternate function output

RTC\_ALARM can be configured in output open drain or output push-pull using the control bit ALARMOUTTYPE in the RTC\_TAFCR register.

*Note:* Once RTC\_ALARM is enabled, it has priority over RTC\_CALIB (COE bit is don't care on RTC\_AF1).

When RTC\_CALIB or RTC\_ALARM is selected, RTC\_AF1 is automatically configured in output alternate function.

## 26.4 RTC and low-power modes

**Table 120. Effect of low-power modes on RTC**

| Mode    | Description                                                                                                                                                                   |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sleep   | No effect<br>RTC interrupts cause the device to exit the Sleep mode.                                                                                                          |
| Stop    | The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC time stamp event, and RTC Wake-up cause the device to exit the Stop mode.    |
| Standby | The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC time stamp event, and RTC Wake-up cause the device to exit the Standby mode. |

## 26.5 RTC interrupts

All RTC interrupts are connected to the EXTI controller.

To enable the RTC Alarm interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 17 in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC\_Alarm IRQ channel in the NVIC.
3. Configure the RTC to generate RTC alarms (Alarm A or Alarm B).

To enable the RTC Wake-up interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 22 in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC\_WKUP IRQ channel in the NVIC.
3. Configure the RTC to generate the RTC wake-up timer event.

To enable the RTC Tamper interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 21 in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC tamper event.

To enable the RTC TimeStamp interrupt, the following sequence is required:

1. Configure and enable the EXTI Line 21 in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the TAMP\_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC timestamp event.

**Table 121. Interrupt control bits**

| Interrupt event                  | Event flag | Enable control bit | Exit the Sleep mode | Exit the Stop mode | Exit the Standby mode |
|----------------------------------|------------|--------------------|---------------------|--------------------|-----------------------|
| Alarm A                          | ALRAF      | ALRAIE             | yes                 | yes <sup>(1)</sup> | yes <sup>(1)</sup>    |
| Alarm B                          | ALRBF      | ALRBIE             | yes                 | yes <sup>(1)</sup> | yes <sup>(1)</sup>    |
| Wake-up                          | WUTF       | WUTIE              | yes                 | yes <sup>(1)</sup> | yes <sup>(1)</sup>    |
| TimeStamp                        | TSF        | TSIE               | yes                 | yes <sup>(1)</sup> | yes <sup>(1)</sup>    |
| Tamper1 detection                | TAMP1F     | TAMPIE             | yes                 | yes <sup>(1)</sup> | yes <sup>(1)</sup>    |
| Tamper2 detection <sup>(2)</sup> | TAMP2F     | TAMPIE             | yes                 | yes <sup>(1)</sup> | yes <sup>(1)</sup>    |

1. Wake-up from STOP and Standby modes is possible only when the RTC clock source is LSE or LSI.
2. If RTC\_TAMPER2 pin is present. Refer to device datasheet pinout.

## 26.6 RTC registers

Refer to [Section 1.1: List of abbreviations for registers for registers](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

### 26.6.1 RTC time register (RTC\_TR)

The RTC\_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 807](#) and [Reading the calendar on page 808](#).

Address offset: 0x00

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

|          |          |    |    |          |    |    |    |      |         |         |    |         |    |    |    |

Bits 31-24 Reserved

Bit 23 Reserved, must be kept at reset value.

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bit 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

**Note:** *This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).*

## 26.6.2 RTC date register (RTC\_DR)

The RTC\_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 807](#) and [Reading the calendar on page 808](#).

Address offset: 0x04

Backup domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

### 26.6.3 RTC control register (RTC\_CR)

Address offset: 0x08

Backup domain reset value: 0x0000 0000

System reset: not affected

| 31       | 30    | 29     | 28     | 27  | 26   | 25    | 24    | 23  | 22        | 21          | 20      | 19     | 18           | 17    | 16    |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **COE**: Calibration output enable

This bit enables the RTC\_CALIB output

0: Calibration output disabled

1: Calibration output enabled

Bits 22:21 **OSEL[1:0]**: Output selection

These bits are used to select the flag to be routed to RTC\_ALARM output

00: Output disabled

01: Alarm A output enabled

10: Alarm B output enabled

11: Wake-up output enabled

Bit 20 **POL**: Output polarity

This bit is used to configure the polarity of RTC\_ALARM output

0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0])

1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]).

Bit 19 **COSEL**: Calibration output selection

When COE=1, this bit selects which signal is output on RTC\_CALIB.

0: Calibration output is 512 Hz

1: Calibration output is 1 Hz

These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV\_A=127 and PREDIV\_S=255). Refer to [Section 26.3.14: Calibration clock output](#)

Bit 18 **BKP**: Backup

This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17 **SUB1H**: Subtract 1 hour (winter time change)

When this bit is set outside initialization mode, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.

Setting this bit has no effect when current hour is 0.

0: No effect

1: Subtracts 1 hour to the current time. This can be used for winter time change.

- Bit 16 **ADD1H**: Add 1 hour (summer time change)  
 When this bit is set, 1 hour is added to the calendar time. This bit is always read as 0.  
 0: No effect  
 1: Adds 1 hour to the current time. This can be used for summer time change outside initialization mode.
- Bit 15 **TSIE**: Timestamp interrupt enable  
 0: Timestamp Interrupt disable  
 1: Timestamp Interrupt enable
- Bit 14 **WUTIE**: Wake-up timer interrupt enable  
 0: Wake-up timer interrupt disabled  
 1: Wake-up timer interrupt enabled
- Bit 13 **ALRBIE**: Alarm B interrupt enable  
 0: Alarm B Interrupt disable  
 1: Alarm B Interrupt enable
- Bit 12 **ALRAIE**: Alarm A interrupt enable  
 0: Alarm A interrupt disabled  
 1: Alarm A interrupt enabled
- Bit 11 **TSE**: Time stamp enable  
 0: Time stamp disable  
 1: Time stamp enable
- Bit 10 **WUTE**: Wake-up timer enable  
 0: Wake-up timer disabled  
 1: Wake-up timer enabled  
*Note: When the wake-up timer is disabled, wait for WUTWF=1 before enabling it again.*
- Bit 9 **ALRBE**: Alarm B enable  
 0: Alarm B disabled  
 1: Alarm B enabled
- Bit 8 **ALRAE**: Alarm A enable  
 0: Alarm A disabled  
 1: Alarm A enabled
- Bit 7 **DCE**: Coarse digital calibration enable  
 0: Digital calibration disabled  
 1: Digital calibration enabled  
 PREDIV\_A must be 6 or greater
- Bit 6 **FMT**: Hour format  
 0: 24 hour/day format  
 1: AM/PM hour format
- Bit 5 **BYPHAD**: Bypass the shadow registers  
 0: Calendar values (when reading from RTC\_SSR, RTC\_TR, and RTC\_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.  
 1: Calendar values (when reading from RTC\_SSR, RTC\_TR, and RTC\_DR) are taken directly from the calendar counters.  
*Note: If the frequency of the APB1 clock is less than seven times the frequency of RTCCLK, BYPSHAD must be set to '1'.*

Bit 4 **REFCKON**: Reference clock detection enable (50 or 60 Hz)

0: Reference clock detection disabled

1: Reference clock detection enabled

*Note: PREDIV\_S must be 0x00FF.*

Bit 3 **TSEDGE**: Timestamp event active edge

0: TIMESTAMP rising edge generates a timestamp event

1: TIMESTAMP falling edge generates a timestamp event

TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting

Bits 2:0 **WUCKSEL[2:0]**: Wake-up clock selection

000: RTC/16 clock is selected

001: RTC/8 clock is selected

010: RTC/4 clock is selected

011: RTC/2 clock is selected

10x: ck\_spre (usually 1 Hz) clock is selected

11x: ck\_spre (usually 1 Hz) clock is selected and  $2^{16}$  is added to the WUT counter value (see note below)

*Note: WUT = Wake-up unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSEL[2:1 = 11].*

*Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC\_ISR/INITF = 1).*

*Bits 2 to 0 of this register can be written only when RTC\_CR WUTE bit = 0 and RTC\_ISR WUTWF bit = 1.*

*It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.*

*ADD1H and SUB1H changes are effective in the next second.*

*To avoid spuriously setting of TSF, TSE must be reset when TSEDGE is changed.*

*This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).*

## 26.6.4 RTC initialization and status register (RTC\_ISR)

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset value: Not affected except INIT, INITF and RSF which are cleared to 0.

|          |         |         |       |       |       |       |       |      |       |       |       |      |        |         |          |
|----------|---------|---------|-------|-------|-------|-------|-------|------|-------|-------|-------|------|--------|---------|----------|

| Res.     | TAMP 2F | TAMP 1F | TSOVF | TSF   | WUTF  | ALRBF | ALRAF | INIT | INITF | RSF   | INITS | SHPF | WUT WF | ALRB WF | ALRA WF  |
|          | rc_w0   | rc_w0   | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rw   | r     | rc_w0 | r     | r    | r      | r       | r        |

Bits 31:17 Reserved

Bit 16 **RECALPF**: Recalibration pending Flag

The RECALPF status flag is automatically set to '1' when software writes to the RTC\_CALR register, indicating that the RTC\_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to '0'. Refer to [Section : Re-calibration on-the-fly](#).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TAMP2F**: TAMPER2 detection flag

This flag is set by hardware when a tamper detection event is detected on tamper input 2. It is cleared by software writing 0.

Bit 13 **TAMP1F**: Tamper detection flag

This flag is set by hardware when a tamper detection event is detected. It is cleared by software writing 0.

Bit 12 **TSOVF**: Timestamp overflow flag

This flag is set by hardware when a timestamp event occurs while TSF is already set. This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a timestamp event occurs immediately before the TSF bit is cleared.

Bit 11 **TSF**: Timestamp flag

This flag is set by hardware when a timestamp event occurs. This flag is cleared by software by writing 0.

Bit 10 **WUTF**: Wake-up timer flag

This flag is set by hardware when the wake-up auto-reload counter reaches 0. This flag is cleared by software by writing 0. This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 9 **ALRBF**: Alarm B flag

This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm B register (RTC\_ALRMBR). This flag is cleared by software by writing 0.

Bit 8 **ALRAF**: Alarm A flag

This flag is set by hardware when the time/date registers (RTC\_TR and RTC\_DR) match the Alarm A register (RTC\_ALRMAR). This flag is cleared by software by writing 0.

Bit 7 **INIT**: Initialization mode

0: Free running mode  
1: Initialization mode used to program time and date register (RTC\_TR and RTC\_DR), and prescaler register (RTC\_PRER). Counters are stopped and start counting from the new value when INIT is reset.

Bit 6 **INITF**: Initialization flag

When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.

0: Calendar registers update is not allowed  
1: Calendar registers update is allowed.

**Bit 5 RSF:** Registers synchronization flag

This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC\_SSRx, RTC\_TRx and RTC\_DRx). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF=1), or when in bypass shadow register mode (BYPSHAD=1). This bit can also be cleared by software.

0: Calendar shadow registers not yet synchronized  
1: Calendar shadow registers synchronized

**Bit 4 INITS:** Initialization status flag

This bit is set by hardware when the calendar year field is different from 0 (backup domain reset value state).

0: Calendar has not been initialized  
1: Calendar has been initialized

**Bit 3 SHPF:** Shift operation pending

0: No shift operation is pending  
1: A shift operation is pending

This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC\_SHIFTR. It is cleared by hardware when the corresponding shift operation has been executed. Writing to SHPF has no effect.

**Bit 2 WUTWF:** Wake-up timer write flag

This bit is set by hardware up to 2 RTCCLK cycles after the WUTE bit has been set to 0 in RTC\_CR, and is cleared up to 2 RTCCLK cycles after the WUTE bit has been set to 1. The wake-up timer values can be changed when WUTE bit is cleared and WUTWF is set.

0: Wake-up timer configuration update not allowed  
1: Wake-up timer configuration update allowed

**Bit 1 ALRBWF:** Alarm B write flag

This bit is set by hardware when Alarm B values can be changed, after the ALRBIE bit has been set to 0 in RTC\_CR.

It is cleared by hardware in initialization mode.

0: Alarm B update not allowed  
1: Alarm B update allowed.

**Bit 0 ALRAWF:** Alarm A write flag

This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC\_CR.

It is cleared by hardware in initialization mode.

0: Alarm A update not allowed  
1: Alarm A update allowed

**Note:** The ALRAF, ALRBF, WUTF and TSF bits are cleared 2 APB clock cycles after programming them to 0.

This register is write protected (except for RTC\_ISR[13:8] bits). The write access procedure is described in [RTC register write protection on page 806](#).

## 26.6.5 RTC prescaler register (RTC\_PRER)

Address offset: 0x10

Backup domain reset value: 0x007F 00FF

System reset: not affected

|          |                |    |    |    |    |    |    |    |               |    |    |    |    |    |    |
|----------|----------------|----|----|----|----|----|----|----|---------------|----|----|----|----|----|----|
| 31       | 30             | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22            | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |                |    |    |    |    |    |    |    | PREDIV_A[6:0] |    |    |    |    |    |    |
|          |                |    |    |    |    |    |    |    | rw            | rw | rw | rw | rw | rw | rw |
| 15       | 14             | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6             | 5  | 4  | 3  | 2  | 1  | 0  |
| Res.     | PREDIV_S[14:0] |    |    |    |    |    |    |    |               |    |    |    |    |    |    |
|          | rw             | rw | rw | rw | rw | rw | rw | rw | rw            | rw | rw | rw | rw | rw | rw |

Bits 31:24 Reserved

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **PREDIV\_A[6:0]**: Asynchronous prescaler factor

This is the asynchronous division factor:

$ck\_apre\ frequency = RTCCLK\ frequency / (PREDIV\_A + 1)$

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **PREDIV\_S[14:0]**: Synchronous prescaler factor

This is the synchronous division factor:

$ck\_spre\ frequency = ck\_apre\ frequency / (PREDIV\_S + 1)$

**Note:** This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to [Calendar initialization and configuration on page 807](#)

This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).

## 26.6.6 RTC wake-up timer register (RTC\_WUTR)

Address offset: 0x14

Backup domain reset value: 0x0000 FFFF

System reset: not affected

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| WUT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved

Bits 15:0 **WUT[15:0]**: Wake-up auto-reload value bits

When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck\_wut cycles. The ck\_wut period is selected through WUCKSEL[2:0] bits of the RTC\_CR register

When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

*Note: The first assertion of WUTF occurs (WUT+1) ck\_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] = 011 (RTCCLK/2) is forbidden.*

*Note: This register can be written only when WUTWF is set to 1 in RTC\_ISR.*

*This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).*

## 26.6.7 RTC calibration register (RTC\_CALIBR)

Address offset: 0x18

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |    |    |    |    |    |    |    |     |          |    |         |    |    |    |    |
|----------|----|----|----|----|----|----|----|-----|----------|----|---------|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22       | 21 | 20      | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |     |          |    |         |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7   | 6        | 5  | 4       | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | DCS | Reserved |    | DC[4:0] |    |    |    |    |
|          |    |    |    |    |    |    |    | rw  |          |    | rw      | rw | rw | rw | rw |

Bits 31:8 Reserved

Bit 7 **DCS**: Digital calibration sign

0: Positive calibration: calendar update frequency is increased

1: Negative calibration: calendar update frequency is decreased

Bits 6:5 Reserved, must be kept at reset value.

Bits 4:0 **DC[4:0]**: Digital calibration

DCS = 0 (positive calibration)

00000: + 0 ppm

00001: + 4 ppm (rounded value)

00010: + 8 ppm (rounded value)

..

11111: + 126 ppm (rounded value)

DCS = 1 (negative calibration)

00000: -0 ppm

00001: -2 ppm (rounded value)

00010: -4 ppm (rounded value)

..

11111: -63 ppm (rounded value)

Refer to [Case of RTCCLK=32.768 kHz and PREDIV\\_A+1=128 on page 811](#) for the exact step value.

**Note:** This register can be written in initialization mode only ( $RTC\_ISR/INITF = '1'$ ).  
 This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).

### 26.6.8 RTC alarm A register (RTC\_ALRMAR)

Address offset: 0x1C

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |          |         |    |          |    |    |    |      |         |         |    |         |    |    |    |
|------|----------|---------|----|----------|----|----|----|------|---------|---------|----|---------|----|----|----|
| 31   | 30       | 29      | 28 | 27       | 26 | 25 | 24 | 23   | 22      | 21      | 20 | 19      | 18 | 17 | 16 |
| MSK4 | WDSEL    | DT[1:0] |    | DU[3:0]  |    |    |    | MSK3 | PM      | HT[1:0] |    | HU[3:0] |    |    |    |
| rw   | rw       | rw      | rw | rw       | rw | rw | rw | rw   | rw      | rw      | rw | rw      | rw | rw | rw |
| 15   | 14       | 13      | 12 | 11       | 10 | 9  | 8  | 7    | 6       | 5       | 4  | 3       | 2  | 1  | 0  |
| MSK2 | MNT[2:0] |         |    | MNU[3:0] |    |    |    | MSK1 | ST[2:0] |         |    | SU[3:0] |    |    |    |
| rw   | rw       | rw      | rw | rw       | rw | rw | rw | rw   | rw      | rw      | rw | rw      | rw | rw | rw |

Bit 31 **MSK4**: Alarm A date mask  
 0: Alarm A set if the date/day match  
 1: Date/day don't care in Alarm A comparison

Bit 30 **WDSEL**: Week day selection  
 0: DU[3:0] represents the date units  
 1: DU[3:0] represents the week day. DT[1:0] is don't care.

Bits 29:28 **DT[1:0]**: Date tens in BCD format.

Bits 27:24 **DU[3:0]**: Date units or day in BCD format.

Bit 23 **MSK3**: Alarm A hours mask  
 0: Alarm A set if the hours match  
 1: Hours don't care in Alarm A comparison

Bit 22 **PM**: AM/PM notation  
 0: AM or 24-hour format  
 1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

Bits 19:16 **HU[3:0]**: Hour units in BCD format.

Bit 15 **MSK2**: Alarm A minutes mask  
 0: Alarm A set if the minutes match  
 1: Minutes don't care in Alarm A comparison

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.

Bits 11:8 **MNU[3:0]**: Minute units in BCD format.

Bit 7 **MSK1**: Alarm A seconds mask  
 0: Alarm A set if the seconds match  
 1: Seconds don't care in Alarm A comparison

Bits 6:4 **ST[2:0]**: Second tens in BCD format.

Bits 3:0 **SU[3:0]**: Second units in BCD format.

**Note:** This register can be written only when *ALRAWF* is set to 1 in *RTC\_ISR*, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).

### 26.6.9 RTC alarm B register (RTC\_ALRMBR)

Address offset: 0x20

Backup domain reset value: 0x0000 0000

System reset: not affected

|      |       |         |    |         |    |    |    |      |    |         |    |         |    |    |    |

| rw   | rw       | rw | rw | rw       | rw | rw | rw | rw   | rw      | rw | rw | rw      | rw | rw | rw |

Bit 31 **MSK4**: Alarm B date mask

0: Alarm B set if the date and day match

1: Date and day don't care in Alarm B comparison

Bit 30 **WDSEL**: Week day selection

0: DU[3:0] represents the date units

1: DU[3:0] represents the week day. DT[1:0] is don't care.

Bits 29:28 **DT[1:0]**: Date tens in BCD format

Bits 27:24 **DU[3:0]**: Date units or day in BCD format

Bit 23 **MSK3**: Alarm B hours mask

0: Alarm B set if the hours match

1: Hours don't care in Alarm B comparison

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 **MSK2**: Alarm B minutes mask

0: Alarm B set if the minutes match

1: Minutes don't care in Alarm B comparison

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 **MSK1**: Alarm B seconds mask

0: Alarm B set if the seconds match

1: Seconds don't care in Alarm B comparison

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

**Note:** This register can be written only when ALRBWF is set to 1 in RTC\_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#).

### 26.6.10 RTC write protection register (RTC\_WPR)

Address offset: 0x24

Backup domain reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7   | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | KEY |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | w   | w  | w  | w  | w  | w  | w  | w  |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **KEY**: Write protection key

This byte is written by software.

Reading this byte always returns 0x00.

Refer to [RTC register write protection](#) for a description of how to unlock RTC register write protection.

### 26.6.11 RTC sub second register (RTC\_SSR)

Address offset: 0x28

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r        | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| SS[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r        | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 Reserved

Bits 15:0 **SS**: Sub second value

SS[15:0] is the value in the synchronous prescaler's counter. The fraction of a second is given by the formula below:

$$\text{Second fraction} = (\text{PREDIV\_S} - \text{SS}) / (\text{PREDIV\_S} + 1)$$

**Note:** SS can be larger than PREDIV\_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC\_TR/RTC\_DR.

## 26.6.12 RTC shift control register (RTC\_SHIFTR)

Address offset: 0x2C

Backup domain reset value: 0x0000 0000

System reset: not affected

|       |             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31    | 30          | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ADD1S | Reserved    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w     | r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15    | 14          | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Res.  | SUBFS[14:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r     | w           | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |

Bit 31 **ADD1S**: Add one second

0: No effect

1: Add one second to the clock/calendar

This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC\_ISR).

This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved

Bits 14:0 **SUBFS**: Subtract a fraction of a second

These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC\_ISR).

The value which is written to SUBFS is added to the synchronous prescaler's counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:

Delay (seconds) = SUBFS / ( PREDIV\_S + 1 )

A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:

Advance (seconds) = ( 1 - ( SUBFS / ( PREDIV\_S + 1 ) ) ) .

*Note: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF=1 to be sure that the shadow registers have been updated with the shifted time.*

Refer to [Section 26.3.8: RTC synchronization](#).

*Note: This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#)*

## 26.6.13 RTC time stamp time register (RTC\_TSTR)

Address offset: 0x30

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |    |    |    |    |    |    |    |    |    |         |    |         |    |    |    |

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PM**: AM/PM notation

0: AM or 24-hour format

1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format.

Bits 19:16 **HU[3:0]**: Hour units in BCD format.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format.

Bits 11:8 **MNU[3:0]**: Minute units in BCD format.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format.

Bits 3:0 **SU[3:0]**: Second units in BCD format.

**Note:** The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

## 26.6.14 RTC time stamp date register (RTC\_TSDR)

Address offset: 0x34

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |    |    |    |         |    |    |    |          |    |    |         |    |         |    |    |
|----------|----|----|----|---------|----|----|----|----------|----|----|---------|----|---------|----|----|
| 31       | 30 | 29 | 28 | 27      | 26 | 25 | 24 | 23       | 22 | 21 | 20      | 19 | 18      | 17 | 16 |
| Reserved |    |    |    |         |    |    |    |          |    |    |         |    |         |    |    |
| 15       | 14 | 13 | 12 | 11      | 10 | 9  | 8  | 7        | 6  | 5  | 4       | 3  | 2       | 1  | 0  |
| WDU[1:0] |    |    | MT | MU[3:0] |    |    |    | Reserved |    |    | DT[1:0] |    | DU[3:0] |    |    |
| r        | r  | r  | r  | r       | r  | r  | r  |          |    |    | r       | r  | r       | r  | r  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:13 **WDU[1:0]**: Week day units

Bit 12 **MT**: Month tens in BCD format

Bits 11:8 **MU[3:0]**: Month units in BCD format

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **DT[1:0]**: Date tens in BCD format

Bit 3:0 **DU[3:0]**: Date units in BCD format

**Note:** The content of this register is valid only when TSF is set to 1 in RTC\_ISR. It is cleared when TSF bit is reset.

### 26.6.15 RTC timestamp sub second register (RTC\_TSSSR)

Address offset: 0x38

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r        | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| SS[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r        | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 Reserved

Bits 15:0 **SS**: Sub second value

SS[15:0] is the value of the synchronous prescaler's counter when the timestamp event occurred.

*Note:* The content of this register is valid only when RTC\_ISR/TSF is set. It is cleared when the RTC\_ISR/TSF bit is reset.

### 26.6.16 RTC calibration register (RTC\_CALR)

Address offset: 0x3C

Backup domain reset value: 0x0000 0000

System reset: not affected

|          |       |        |          |    |    |    |           |    |    |    |    |    |    |    |    |
|----------|-------|--------|----------|----|----|----|-----------|----|----|----|----|----|----|----|----|
| 31       | 30    | 29     | 28       | 27 | 26 | 25 | 24        | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |       |        |          |    |    |    |           |    |    |    |    |    |    |    |    |
| r        | r     | r      | r        | r  | r  | r  | r         | r  | r  | r  | r  | r  | r  | r  | r  |
| 15       | 14    | 13     | 12       | 11 | 10 | 9  | 8         | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CALP     | CALW8 | CALW16 | Reserved |    |    |    | CALM[8:0] |    |    |    |    |    |    |    |    |
| rw       | rw    | rw     | r        | r  | r  | r  | rw        | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved

Bit 15 **CALP**: Increase frequency of RTC by 488.5 ppm

0: No RTCCLK pulses are added.

1: One RTCCLK pulse is effectively inserted every  $2^{11}$  pulses (frequency increased by 488.5 ppm).

This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCLK pulses added during a 32-second window is calculated as follows:  $(512 * CALP) - CALM$ .

Refer to [Section 26.3.11: RTC smooth digital calibration](#).

Bit 14 **CALW8**: Use an 8-second calibration cycle period

When CALW8 is set to '1', the 8-second calibration cycle period is selected.

CALM[1:0] are stuck at "00" when CALW8='1'.

Refer to [Section 26.3.11: RTC smooth digital calibration](#).

Bit 13 **CALW16**: Use a 16-second calibration cycle period

When CALW16 is set to '1', the 16-second calibration cycle period is selected. This bit must not be set to '1' if CALW8=1.

*Note:* CALM[0] is stuck at '0' when CALW16='1'.

Refer to [Section 26.3.11: RTC smooth digital calibration](#).

Bits 12:9 Reserved

Bits 8:0 **CALM[8:0]**: Calibration minus

The frequency of the calendar is reduced by masking CALM out of  $2^{20}$  RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP.

See [Section 26.3.11: RTC smooth digital calibration on page 812](#).

*Note:* This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#)

## 26.6.17 RTC tamper and alternate function configuration register (RTC\_TAFCR)

Address offset: 0x40

Backup domain reset value: 0x0000 0000

System reset: not affected

| 31             | 30                 | 29 | 28           | 27 | 26            | 25 | 24 | 23         | 22       | 21 | 20 | 19            | 18               | 17          | 16             |

Bits 31:19 Reserved. Always read as 0.

Bit 18 **ALARMOUTTYPE**: RTC\_ALARM output type

- 0: RTC\_ALARM is an open-drain output
- 1: RTC\_ALARM is a push-pull output

Bit 17 **TSINSEL**: TIMESTAMP mapping

- 0: RTC\_AF1 used as TIMESTAMP
- 1: RTC\_AF2 used as TIMESTAMP

Bit 16 **TAMP1INSEL**: TAMPER1 mapping

- 0: RTC\_AF1 used as TAMPER1
- 1: RTC\_AF2 used as TAMPER1

*Note: TAMP1E must be reset when TAMP1INSEL is changed to avoid unwanted setting of TAMP1F.*

Bit 15 **TAMPPUDIS**: TAMPER pull-up disable

This bit determines if each of the tamper pins are pre-charged before each sample.

- 0: Precharge tamper pins before sampling (enable internal pull-up)
- 1: Disable precharge of tamper pins

*Note:*

Bits 14:13 **TAMPPRCH[1:0]**: Tamper precharge duration

These bit determines the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the tamper inputs.

- 0x0: 1 RTCCLK cycle
- 0x1: 2 RTCCLK cycles
- 0x2: 4 RTCCLK cycles
- 0x3: 8 RTCCLK cycles

Bits 12:11 **TAMPFLT[1:0]**: Tamper filter count

These bits determines the number of consecutive samples at the specified level (TAMP\*TRG) necessary to activate a Tamper event. TAMPFLT is valid for each of the tamper inputs.

0x0: Tamper is activated on edge of tamper input transitions to the active level (no internal pull-up on tamper input).

0x1: Tamper is activated after 2 consecutive samples at the active level.

0x2: Tamper is activated after 4 consecutive samples at the active level.

0x3: Tamper is activated after 8 consecutive samples at the active level.

Bits 10:8 **TAMPFREQ[2:0]**: Tamper sampling frequency

Determines the frequency at which each of the tamper inputs are sampled.

0x0: RTCCLK / 32768 (1 Hz when RTCCLK = 32768 Hz)

0x1: RTCCLK / 16384 (2 Hz when RTCCLK = 32768 Hz)

0x2: RTCCLK / 8192 (4 Hz when RTCCLK = 32768 Hz)

0x3: RTCCLK / 4096 (8 Hz when RTCCLK = 32768 Hz)

0x4: RTCCLK / 2048 (16 Hz when RTCCLK = 32768 Hz)

0x5: RTCCLK / 1024 (32 Hz when RTCCLK = 32768 Hz)

0x6: RTCCLK / 512 (64 Hz when RTCCLK = 32768 Hz)

0x7: RTCCLK / 256 (128 Hz when RTCCLK = 32768 Hz)

Bit 7 **TAMPTS**: Activate timestamp on tamper detection event

0: Tamper detection event does not cause a timestamp to be saved

1: Save timestamp on tamper detection event

TAMPTS is valid even if TSE=0 in the RTC\_CR register.

## Bits 6:5 Reserved. Always read as 0.

Bit 4 **TAMP2TRG**: Active level for tamper 2

if TAMPFLT != 00

0: TAMPER2 staying low triggers a tamper detection event.

1: TAMPER2 staying high triggers a tamper detection event.

if TAMPFLT = 00:

0: TAMPER2 rising edge triggers a tamper detection event.

1: TAMPER2 falling edge triggers a tamper detection event.

Bit 3 **TAMP2E**: Tamper 2 detection enable

0: Tamper 2 detection disabled

1: Tamper 2 detection enabled

Bit 2 **TAMPIE**: Tamper interrupt enable

0: Tamper interrupt disabled

1: Tamper interrupt enabled

Bit 1 **TAMP1TRG**: Active level for tamper 1

if TAMPFLT != 00

0: TAMPER1 staying low triggers a tamper detection event.

1: TAMPER1 staying high triggers a tamper detection event.

if TAMPFLT = 00:

0: TAMPER1 rising edge triggers a tamper detection event.

1: TAMPER1 falling edge triggers a tamper detection event.

**Caution:** When TAMPFLT = 0, TAMPxE must be reset when TAMPxTRG is changed to avoid spuriously setting TAMPxF.

Bit 0 **TAMP1E**: Tamper 1 detection enable

0: Tamper 1 detection disabled

1: Tamper 1 detection enabled

## 26.6.18 RTC alarm A sub second register (RTC\_ALRMASSR)

Address offset: 0x44

Backup domain reset value: 0x0000 0000

System reset: not affected

Bits 31:28 Reserved

Bits 27:24 **MASKSS[3:0]**: Mask the most-significant bits starting at this bit

0: No comparison on sub seconds for Alarm A. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

1: SS[14:1] are don't care in Alarm A comparison. Only SS[0] is compared.

2: SS[14:2] are don't care in Alarm A comparison. Only SS[1:0] are compared.

3: SS[14:3] are don't care in Alarm A comparison. Only SS[2:0] are compared.

...

12: SS[14:12] are don't care in Alarm A comparison. SS[11:0] are compared.

13: SS[14:13] are don't care in Alarm A comparison. SS[12:0] are compared.

14: SS[14] is don't care in Alarm A comparison. SS[13:0] are compared.

15: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved

Bits 14:0 **SS[14:0]**: Sub seconds value

This value is compared with the contents of the synchronous prescaler's counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.

**Note:** This register can be written only when ALRAE is reset in RTC\_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 806](#)

### 26.6.19 RTC alarm B sub second register (RTC\_ALRMBSSR)

Address offset: 0x48

Backup domain reset value: 0x0000 0000

System reset: not affected

Bits 31:28 Reserved

Bits 27:24 **MASKSS[3:0]**: Mask the most-significant bits starting at this bit

0x0: No comparison on sub seconds for Alarm B. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

0x1: SS[14:1] are don't care in Alarm B comparison. Only SS[0] is compared.

0x2: SS[14:2] are don't care in Alarm B comparison. Only SS[1:0] are compared.

0x3: SS[14:3] are don't care in Alarm B comparison. Only SS[2:0] are compared.

...

0xC: SS[14:12] are don't care in Alarm B comparison. SS[11:0] are compared.

0xD: SS[14:13] are don't care in Alarm B comparison. SS[12:0] are compared.

0xE: SS[14] is don't care in Alarm B comparison. SS[13:0] are compared.

0xF: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved

Bits 14:0 **SS[14:0]**: Sub seconds value

This value is compared with the contents of the synchronous prescaler's counter to determine if Alarm B is to be activated. Only bits 0 up to MASKSS-1 are compared.

**Note:** This register can be written only when ALRBIE is reset in RTC\_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [Section : RTC register write protection](#)

## 26.6.20 RTC backup registers (RTC\_BKPxR)

Address offset: 0x50 to 0x9C

Backup domain reset value: 0x0000 0000

System reset: not affected

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| BKP[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| BKP[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | W  | rW | rW |

Bits 31:0 BKP[31:0]

The application can write or read data to and from these registers.

They are powered-on by V<sub>BAT</sub> when V<sub>DD</sub> is switched off, so that they are not reset by System reset, and their contents remain valid when the device operates in low-power mode.

This register is reset on a tamper detection event, as long as TAMPxP=1.

## 26.6.21 RTC register map

Table 122. RTC register map and reset values

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21            | 20         | 19 | 18      | 17    | 16       | 15             | 14        | 13       | 12    | 11       | 10     | 9     | 8        | 7        | 6     | 5        | 4       | 3        | 2       | 1      | 0            |   |   |   |   |   |   |   |   |

|                 | Reset value      | 0         | 0        | 0        | 0  | 0           | 0  | 0  | 0  | 0        | 0  | 0            | 0  | 0       | 0          | 0         | 0             | 0        | 0            | 0        | 0             | 0         | 0        | 0        | 0 | 0        | 0      | 0      | 0        | 0      | 0 | 0 | 0 |   |   |   |
|                 | to<br>RTC_BKP19R | BKP[31:0] |          |          |    |             |    |    |    |          |    |              |    |         |            |           |               |          |              |          |               |           |          |          |   |          |        |        |          |        |   |   |   |   |   |   |
|                 | Reset value      | 0         | 0        | 0        | 0  | 0           | 0  | 0  | 0  | 0        | 0  | 0            | 0  | 0       | 0          | 0         | 0             | 0        | 0            | 0        | 0             | 0         | 0        | 0        | 0 | 0        | 0      | 0      | 0        | 0      | 0 | 0 | 0 | 0 |   |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

**Caution:** In [Table 122](#), the reset value is the value after a backup domain reset. The majority of the registers are not affected by a system reset. For more information, please refer to [Section 26.3.7: Resetting the RTC](#).

## 27 Inter-integrated circuit (I2C) interface

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 27.1 I<sup>2</sup>C introduction

I<sup>2</sup>C (inter-integrated circuit) bus Interface serves as an interface between the microcontroller and the serial I<sup>2</sup>C bus. It provides multimaster capability, and controls all I<sup>2</sup>C bus-specific sequencing, protocol, arbitration and timing. It supports the standard mode (Sm, up to 100 kHz) and Fm mode (Fm, up to 400 kHz).

It may be used for a variety of purposes, including CRC generation and verification, SMBus (system management bus) and PMBus (power management bus).

Depending on specific device implementation DMA capability can be available for reduced CPU overload.

### 27.2 I<sup>2</sup>C main features

- Parallel-bus/I<sup>2</sup>C protocol converter
- Multimaster capability: the same interface can act as Master or Slave
- I<sup>2</sup>C Master features:
  - Clock generation
  - Start and Stop generation
- I<sup>2</sup>C Slave features:
  - Programmable I<sup>2</sup>C Address detection
  - Dual Addressing Capability to acknowledge 2 slave addresses
  - Stop bit detection
- Generation and detection of 7-bit/10-bit addressing and General Call
- Supports different communication speeds:
  - Standard Speed (up to 100 kHz)
  - Fast Speed (up to 400 kHz)
- Analog noise filter
- Programmable digital noise filter for STM32F42xxx and STM32F43xxx
- Status flags:
  - Transmitter/Receiver mode flag
  - End-of-Byte transmission flag
  - I<sup>2</sup>C busy flag
- Error flags:
  - Arbitration lost condition for master mode
  - Acknowledgment failure after address/ data transmission
  - Detection of misplaced start or stop condition
  - Overrun/Underrun if clock stretching is disabled
- 2 Interrupt vectors:

- 1 Interrupt for successful address/ data communication
  - 1 Interrupt for error condition
- Optional clock stretching
- 1-byte buffer with DMA capability
- Configurable PEC (packet error checking) generation or verification:
  - PEC value can be transmitted as last byte in Tx mode
  - PEC error checking for last received byte
- SMBus 2.0 Compatibility:
  - 25 ms clock low timeout delay
  - 10 ms master cumulative clock low extend time
  - 25 ms slave cumulative clock low extend time
  - Hardware PEC generation/verification with ACK control
  - Address Resolution Protocol (ARP) supported
- PMBus Compatibility

*Note:* Some of the above features may not be available in certain products. The user should refer to the product data sheet, to identify the specific features supported by the I<sup>2</sup>C interface implementation.

## 27.3 I<sup>2</sup>C functional description

In addition to receiving and transmitting data, this interface converts it from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I<sup>2</sup>C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz) or fast (up to 400 kHz) I<sup>2</sup>C bus.

### 27.3.1 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master, after it generates a START condition and from master to slave, if an arbitration loss or a Stop generation occurs, allowing multimaster capability.

#### Communication flow

In Master mode, the I<sup>2</sup>C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a start condition and ends with a stop condition. Both start and stop conditions are generated in master mode by software.

In Slave mode, the interface is capable of recognizing its own addresses (7 or 10-bit), and the General Call address. The General Call address detection may be enabled or disabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the start condition contain the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in Master mode.

A 9th clock pulse follows the 8 clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter. Refer to [Figure 238](#).

**Figure 238. I<sup>2</sup>C bus protocol**

Acknowledge may be enabled or disabled by software. The I<sup>2</sup>C interface addresses (dual addressing 7-bit/ 10-bit and/or general call address) can be selected by software.

The block diagram of the I<sup>2</sup>C interface is shown in [Figure 239](#).

Figure 239. I<sup>2</sup>C block diagram for STM32F40x/41x

**Figure 240. I<sup>2</sup>C block diagram for STM32F42x/43x**

1. SMBA is an optional signal in SMBus mode. This signal is not applicable if SMBus is disabled.

### 27.3.2 I<sup>2</sup>C slave mode

By default the I<sup>2</sup>C interface operates in Slave mode. To switch from default Slave mode to Master mode a Start condition generation is needed.

The peripheral input clock must be programmed in the I2C\_CR2 register in order to generate correct timings. The peripheral input clock frequency must be at least:

- 2 MHz in Sm mode
- 4 MHz in Fm mode

As soon as a start condition is detected, the address is received from the SDA line and sent to the shift register. Then it is compared with the address of the interface (OAR1) and with OAR2 (if ENDUAL=1) or the General Call address (if ENGCG = 1).

**Note:** In 10-bit addressing mode, the comparison includes the header sequence (11110xx0), where xx denotes the two most significant bits of the address.

**Header or address not matched:** the interface ignores it and waits for another Start condition.

**Header matched** (10-bit mode only): the interface generates an acknowledge pulse if the ACK bit is set and waits for the 8-bit slave address.

**Address matched:** the interface generates in sequence:

- An acknowledge pulse if the ACK bit is set
- The ADDR bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.
- If ENDUAL=1, the software has to read the DUALF bit to check which slave address has been acknowledged.

In 10-bit mode, after receiving the address sequence the slave is always in Receiver mode. It enters Transmitter mode on receiving a repeated Start condition followed by the header sequence with matching address bits and the least significant bit set (11110xx1).

The TRA bit indicates whether the slave is in Receiver or Transmitter mode.

### Slave transmitter

Following the address reception and after clearing ADDR, the slave sends bytes from the DR register to the SDA line via the internal shift register.

The slave stretches SCL low until ADDR is cleared and DR filled with the data to be sent (see [Figure 241](#) Transfer sequencing EV1 EV3).

When the acknowledge pulse is received:

- The TxE bit is set by hardware with an interrupt if the ITEVFEN and the ITBUFEN bits are set.

If TxE is set and some data were not written in the I2C\_DR register before the end of the next data transmission, the BTF bit is set and the interface waits until BTF is cleared by a read to I2C\_SR1 followed by a write to the I2C\_DR register, stretching SCL low.

Figure 241. Transfer sequence diagram for slave transmitter

1. The EV1 and EV3\_1 events stretch SCL low until the end of the corresponding software sequence.
2. The EV3 event stretches SCL low if the software sequence is not completed before the end of the next byte transmission.

### Slave receiver

Following the address reception and after clearing ADDR, the slave receives bytes from the SDA line into the DR register via the internal shift register. After each byte the interface generates in sequence:

- An acknowledge pulse if the ACK bit is set
- The RxNE bit is set by hardware and an interrupt is generated if the ITEVFEN and ITBUFEN bit is set.

If RxNE is set and the data in the DR register is not read before the end of the next data reception, the BTF bit is set and the interface waits until BTF is cleared by a read from the I2C\_DR register, stretching SCL low (see [Figure 242](#) Transfer sequencing).

**Figure 242. Transfer sequence diagram for slave receiver**

1. The EV1 event stretches SCL low until the end of the corresponding software sequence.
2. The EV2 event stretches SCL low if the software sequence is not completed before the end of the next byte reception.
3. After checking the SR1 register content, the user should perform the complete clearing sequence for each flag found set.  
Thus, for ADDR and STOPF flags, the following sequence is required inside the I2C interrupt routine:  

```

READ SR1
if (ADDR == 1) {READ SR1; READ SR2}
if (STOPF == 1) {READ SR1; WRITE CR1}

```

The purpose is to make sure that both ADDR and STOPF flags are cleared if both are found set.

### Closing slave communication

After the last data byte is transferred a Stop Condition is generated by the master. The interface detects this condition and sets:

- The STOPF bit and generates an interrupt if the ITEVFEN bit is set.

The STOPF bit is cleared by a read of the SR1 register followed by a write to the CR1 register (see EV4 in [Figure 242](#)).

### 27.3.3 I<sup>2</sup>C master mode

In Master mode, the I<sup>2</sup>C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a Start condition and ends with a Stop condition. Master mode is selected as soon as the Start condition is generated on the bus with a START bit.

The following is the required sequence in master mode.

- Program the peripheral input clock in I2C\_CR2 register in order to generate correct timings
- Configure the clock control registers
- Configure the rise time register
- Program the I2C\_CR1 register to enable the peripheral
- Set the START bit in the I2C\_CR1 register to generate a Start condition

The peripheral input clock frequency must be at least:

- 2 MHz in Sm mode
- 4 MHz in Fm mode

### SCL master clock generation

The CCR bits are used to generate the high and low level of the SCL clock, starting from the generation of the rising and falling edge (respectively). As a slave may stretch the SCL line, the peripheral checks the SCL input from the bus at the end of the time programmed in TRISE bits after rising edge generation.

- If the SCL line is low, it means that a slave is stretching the bus, and the high level counter stops until the SCL line is detected high. This allows to guarantee the minimum HIGH period of the SCL clock parameter.
- If the SCL line is high, the high level counter keeps on counting.

Indeed, the feedback loop from the SCL rising edge generation by the peripheral to the SCL rising edge detection by the peripheral takes time even if no slave stretches the clock. This loopback duration is linked to the SCL rising time (impacting SCL VIH input detection), plus delay due to the noise filter present on the SCL input path, plus delay due to internal SCL input synchronization with APB clock. The maximum time used by the feedback loop is programmed in the TRISE bits, so that the SCL frequency remains stable whatever the SCL rising time.

### Start condition

Setting the START bit causes the interface to generate a Start condition and to switch to Master mode (MSL bit set) when the BUSY bit is cleared.

*Note: In master mode, setting the START bit causes the interface to generate a ReStart condition at the end of the current byte transfer.*

Once the Start condition is sent:

- The SB bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a write in the DR register with the Slave address (see [Figure 243](#) and [Figure 244](#) Transfer sequencing EV5).

### Slave address transmission

Then the slave address is sent to the SDA line via the internal shift register.

- In 10-bit addressing mode, sending the header sequence causes the following event:
  - The ADD10 bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a write in the DR register with the second address byte (see [Figure 243](#) and [Figure 244](#) Transfer sequencing).

- The ADDR bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a read of the SR2 register (see [Figure 243](#) and [Figure 244](#) Transfer sequencing).

- In 7-bit addressing mode, one address byte is sent.

As soon as the address byte is sent,

- The ADDR bit is set by hardware and an interrupt is generated if the ITEVFEN bit is set.

Then the master waits for a read of the SR1 register followed by a read of the SR2 register (see [Figure 243](#) and [Figure 244](#) Transfer sequencing).

The master can decide to enter Transmitter or Receiver mode depending on the LSB of the slave address sent.

- In 7-bit addressing mode,
  - To enter Transmitter mode, a master sends the slave address with LSB reset.
  - To enter Receiver mode, a master sends the slave address with LSB set.
- In 10-bit addressing mode,
  - To enter Transmitter mode, a master sends the header (11110xx0) and then the slave address, (where xx denotes the two most significant bits of the address).
  - To enter Receiver mode, a master sends the header (11110xx0) and then the slave address. Then it should send a repeated Start condition followed by the header (11110xx1), (where xx denotes the two most significant bits of the address).

The TRA bit indicates whether the master is in Receiver or Transmitter mode.

### Master transmitter

Following the address transmission and after clearing ADDR, the master sends bytes from the DR register to the SDA line via the internal shift register.

The master waits until the first data byte is written into I2C\_DR (see [Figure 243](#) Transfer sequencing EV8\_1).

When the acknowledge pulse is received, the TxE bit is set by hardware and an interrupt is generated if the ITEVFEN and ITBUFEN bits are set.

If TxE is set and a data byte was not written in the DR register before the end of the last data transmission, BTF is set and the interface waits until BTF is cleared by a write to I2C\_DR, stretching SCL low.

### Closing the communication

After the last byte is written to the DR register, the STOP bit is set by software to generate a Stop condition (see [Figure 243](#) Transfer sequencing EV8\_2). The interface automatically goes back to slave mode (MSL bit cleared).

*Note:* Stop condition should be programmed during EV8\_2 event, when either TxE or BTF is set.

Figure 243. Transfer sequence diagram for master transmitter

1. The EV5, EV6, EV9, EV8\_1 and EV8\_2 events stretch SCL low until the end of the corresponding software sequence.
2. The EV8 event stretches SCL low if the software sequence is not complete before the end of the next byte transmission.

### Master receiver

Following the address transmission and after clearing ADDR, the I<sup>2</sup>C interface enters Master Receiver mode. In this mode the interface receives bytes from the SDA line into the DR register via the internal shift register. After each byte the interface generates in sequence:

1. An acknowledge pulse if the ACK bit is set
2. The RxNE bit is set and an interrupt is generated if the ITEVFEN and ITBUFEN bits are set (see [Figure 244](#) Transfer sequencing EV7).

If the RxNE bit is set and the data in the DR register is not read before the end of the last data reception, the BTF bit is set by hardware and the interface waits until BTF is cleared by a read in the DR register, stretching SCL low.

### Closing the communication

The master sends a NACK for the last byte received from the slave. After receiving this NACK, the slave releases the control of the SCL and SDA lines. Then the master can send a Stop/Restart condition.

1. To generate the nonacknowledge pulse after the last received data byte, the ACK bit must be cleared just after reading the second last data byte (after second last RxNE event).
2. In order to generate the Stop/Restart condition, software must set the STOP/START bit after reading the second last data byte (after the second last RxNE event).
3. In case a single byte has to be received, the Acknowledge disable is made during EV6 (before ADDR flag is cleared) and the STOP condition generation is made after EV6.

After the Stop condition generation, the interface goes automatically back to slave mode (MSL bit cleared).

**Figure 244. Transfer sequence diagram for master receiver**

1. If a single byte is received, it is NA.
2. The EV5, EV6 and EV9 events stretch SCL low until the end of the corresponding software sequence.
3. The EV7 event stretches SCL low if the software sequence is not completed before the end of the next byte reception.
4. The EV7\_1 software sequence must be completed before the ACK pulse of the current byte transfer.

The procedures described below are recommended if the EV7-1 software sequence is not completed before the ACK pulse of the current byte transfer.

These procedures must be followed to make sure:

- The ACK bit is set low on time before the end of the last data reception
- The STOP bit is set high after the last data reception without reception of supplementary data.

#### For 2-byte reception:

- Wait until ADDR = 1 (SCL stretched low until the ADDR flag is cleared)
- Set ACK low, set POS high
- Clear ADDR flag
- Wait until BTF = 1 (Data 1 in DR, Data2 in shift register, SCL stretched low until a data 1 is read)
- Set STOP high
- Read data 1 and 2

**For N > 2 -byte reception, from N-2 data reception**

- Wait until BTF = 1 (data N-2 in DR, data N-1 in shift register, SCL stretched low until data N-2 is read)
- Set ACK low
- Read data N-2
- Wait until BTF = 1 (data N-1 in DR, data N in shift register, SCL stretched low until a data N-1 is read)
- Set STOP high
- Read data N-1 and N

### 27.3.4 Error conditions

The following are the error conditions which may cause communication to fail.

**Bus error (BERR)**

This error occurs when the I<sup>2</sup>C interface detects an external Stop or Start condition during an address or a data transfer. In this case:

- the BERR bit is set and an interrupt is generated if the ITERREN bit is set
- in Slave mode: data are discarded and the lines are released by hardware:
  - in case of a misplaced Start, the slave considers it is a restart and waits for an address, or a Stop condition
  - in case of a misplaced Stop, the slave behaves like for a Stop condition and the lines are released by hardware
- In Master mode: the lines are not released and the state of the current transmission is not affected. It is up to the software to abort or not the current transmission

**Acknowledge failure (AF)**

This error occurs when the interface detects a nonacknowledge bit. In this case:

- the AF bit is set and an interrupt is generated if the ITERREN bit is set
- a transmitter which receives a NACK must reset the communication:
  - If Slave: lines are released by hardware
  - If Master: a Stop or repeated Start condition must be generated by software

**Arbitration lost (ARLO)**

This error occurs when the I<sup>2</sup>C interface detects an arbitration lost condition. In this case

- the ARLO bit is set by hardware (and an interrupt is generated if the ITERREN bit is set)
- the I<sup>2</sup>C Interface goes automatically back to slave mode (the MSL bit is cleared). When the I<sup>2</sup>C loses the arbitration, it is not able to acknowledge its slave address in the same transfer, but it can acknowledge it after a repeated Start from the winning master.
- lines are released by hardware

### Overrun/underrun error (OVR)

An overrun error can occur in slave mode when clock stretching is disabled and the I<sup>2</sup>C interface is receiving data. The interface has received a byte (RxNE=1) and the data in DR has not been read, before the next byte is received by the interface. In this case,

- The last received byte is lost.
- In case of Overrun error, software should clear the RxNE bit and the transmitter should re-transmit the last received byte.

Underrun error can occur in slave mode when clock stretching is disabled and the I<sup>2</sup>C interface is transmitting data. The interface has not updated the DR with the next byte (TxNE=1), before the clock comes for the next byte. In this case,

- The same byte in the DR register is sent again.
- The user should make sure that data received on the receiver side during an underrun error are discarded and that the next bytes are written within the clock low time specified in the I<sup>2</sup>C bus standard.

For the first byte to be transmitted, the DR must be written after ADDR is cleared and before the first SCL rising edge. If not possible, the receiver must discard the first data.

### 27.3.5 Programmable noise filter

The programmable noise filter is available on STM32F42xxx and STM32F43xxx devices only.

In Fm mode, the I<sup>2</sup>C standard requires that spikes are suppressed to a length of 50 ns on SDA and SCL lines.

An analog noise filter is implemented in the SDA and SCL I/Os. This filter is enabled by default and can be disabled by setting the ANOFF bit in the I2C\_FLTR register.

A digital noise filter can be enabled by configuring the DNF[3:0] bits to a non-zero value. This suppresses the spikes on SDA and SCL inputs with a length of up to DNF[3:0] \* T<sub>PCLK1</sub>.

Enabling the digital noise filter increases the SDA hold time by (DNF[3:0] + 1) \* T<sub>PCLK1</sub>.

To be compliant with the maximum hold time of the I<sup>2</sup>C-bus specification version 2.1 (Thd:dat), the DNF bits must be programmed using the constraints shown in [Table 123](#), and assuming that the analog filter is disabled.

**Note:** *DNF[3:0] must only be configured when the I<sup>2</sup>C is disabled (PE = 0). If the analog filter is also enabled, the digital filter is added to the analog filter.*

**Table 123. Maximum DNF[3:0] value to be compliant with Thd:dat(max)**

| PCLK1 frequency              | Maximum DNF value |         |
|------------------------------|-------------------|---------|
|                              | Sm mode           | Fm mode |
| 2 ≤ F <sub>PCLK1</sub> ≤ 5   | 2                 | 0       |
| 5 < F <sub>PCLK1</sub> ≤ 10  | 12                | 0       |
| 10 < F <sub>PCLK1</sub> ≤ 20 | 15                | 1       |
| 20 < F <sub>PCLK1</sub> ≤ 30 | 15                | 7       |

**Table 123. Maximum DNF[3:0] value to be compliant with Thd:dat(max) (continued)**

| PCLK1 frequency          | Maximum DNF value |         |
|--------------------------|-------------------|---------|
|                          | Sm mode           | Fm mode |
| $30 < F_{PCLK1} \leq 40$ | 15                | 13      |
| $40 < F_{PCLK1} \leq 50$ | 15                | 15      |

*Note:* For each frequency range, the constraint is given based on the worst case which is the minimum frequency of the range. Greater DNF values can be used if the system can support maximum hold time violation.

### 27.3.6 SDA/SCL line control

- If clock stretching is enabled:
  - Transmitter mode: If TxNE=1 and BTF=1: the interface holds the clock line low before transmission to wait for the microcontroller to write the byte in the Data register (both buffer and shift register are empty).
  - Receiver mode: If RxNE=1 and BTF=1: the interface holds the clock line low after reception to wait for the microcontroller to read the byte in the Data register (both buffer and shift register are full).
- If clock stretching is disabled in Slave mode:
  - Overrun Error in case of RxNE=1 and no read of DR has been done before the next byte is received. The last received byte is lost.
  - Underrun Error in case TxNE=1 and no write into DR has been done before the next byte must be transmitted. The same byte is sent again.
  - Write Collision not managed.

### 27.3.7 SMBus

#### Introduction

The System Management Bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I<sup>2</sup>C principles of operation. SMBus provides a control bus for system and power management related tasks. A system may use SMBus to pass messages to and from devices instead of toggling individual control lines.

The System Management Bus Specification refers to three types of devices. A *slave* is a device that is receiving or responding to a command. A *master* is a device that issues commands, generates the clocks, and terminates the transfer. A *host* is a specialized master that provides the main interface to the system's CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

#### Similarities between SMBus and I<sup>2</sup>C

- 2-wire bus protocol (1 Clk, 1 Data) + SMBus Alert line optional
- Master-slave communication, Master provides clock
- Multi master capability
- SMBus data format similar to I<sup>2</sup>C 7-bit addressing format ([Figure 238](#)).

## Differences between SMBus and I<sup>2</sup>C

The following table describes the differences between SMBus and I<sup>2</sup>C.

**Table 124. SMBus vs. I<sup>2</sup>C**

| SMBus                                                      | I <sup>2</sup> C                                   |
|------------------------------------------------------------|----------------------------------------------------|
| Max. speed 100 kHz                                         | Max. speed 400 kHz                                 |
| Min. clock speed 10 kHz                                    | No minimum clock speed                             |
| 35 ms clock low timeout                                    | No timeout                                         |
| Logic levels are fixed                                     | Logic levels are V <sub>DD</sub> dependent         |
| Different address types (reserved, dynamic etc.)           | 7-bit, 10-bit and general call slave address types |
| Different bus protocols (quick command, process call etc.) | No bus protocols                                   |

## SMBus application usage

With System Management Bus, a device can provide manufacturer information, tell the system what its model/part number is, save its state for a suspend event, report different types of errors, accept control parameters, and return its status. SMBus provides a control bus for system and power management related tasks.

## Device identification

Any device that exists on the System Management Bus as a slave has a unique address called the Slave Address. For the list of reserved slave addresses, refer to the SMBus specification version. 2.0 (<http://smbus.org/>).

## Bus protocols

The SMBus specification supports up to nine bus protocols. For more details of these protocols and SMBus address types, refer to SMBus specification version. 2.0. These protocols should be implemented by the user software.

## Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. The Address Resolution Protocol (ARP) has the following attributes:

- Address assignment uses the standard SMBus physical layer arbitration mechanism
- Assigned addresses remain constant while device power is applied; address retention through device power loss is also allowed
- No additional SMBus packet overhead is incurred after address assignment. (i.e. subsequent accesses to assigned slave addresses have the same overhead as accesses to fixed address devices.)
- Any SMBus master can enumerate the bus

## Unique device identifier (UDID)

In order to provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique device identifier (UDID).

For the details on 128-bit UDID and more information on ARP, refer to SMBus specification version 2.0.

### SMBus alert mode

SMBus Alert is an optional signal with an interrupt line for devices that want to trade their ability to master for a pin. SMBA is a wired-AND signal just as the SCL and SDA signals are. SMBA is used in conjunction with the SMBus General Call Address. Messages invoked with the SMBus are two bytes long.

A slave-only device can signal the host through SMBA that it wants to talk by setting ALERT bit in I2C\_CR1 register. The host processes the interrupt and simultaneously accesses all SMBA devices through the *Alert Response Address* (known as ARA having a value 0001 100X). Only the device(s) which pulled SMBA low acknowledge the Alert Response Address. This status is identified using SMBALERT Status flag in I2C\_SR1 register. The host performs a modified Receive Byte operation. The 7 bit device address provided by the slave transmit device is placed in the 7 most significant bits of the byte. The eighth bit can be a zero or one.

If more than one device pulls SMBA low, the highest priority (lowest address) device wins communication rights via standard arbitration during the slave address transfer. After acknowledging the slave address the device must disengage its SMBA pull-down. If the host still sees SMBA low when the message transfer is complete, it knows to read the ARA again.

A host which does not implement the SMBA signal may periodically access the ARA.

For more details on SMBus Alert mode, refer to SMBus specification version 2.0.

### Timeout error

There are differences in the timing specifications between I<sup>2</sup>C and SMBus. SMBus defines a clock low timeout, TIMEOUT of 35 ms. Also SMBus specifies TLOW: SEXT as the cumulative clock low extend time for a slave device. SMBus specifies TLOW: MEXT as the cumulative clock low extend time for a master device. For more details on these timeouts, refer to SMBus specification version 2.0.

The status flag Timeout or Tlow Error in I2C\_SR1 shows the status of this feature.

### How to use the interface in SMBus mode

To switch from I<sup>2</sup>C mode to SMBus mode, the following sequence should be performed.

- Set the SMBus bit in the I2C\_CR1 register
- Configure the SMBTYPE and ENARP bits in the I2C\_CR1 register as required for the application

If you want to configure the device as a master, follow the Start condition generation procedure in [Section 27.3.3](#). Otherwise, follow the sequence in [Section 27.3.2](#).

The application has to control the various SMBus protocols by software.

- SMB Device Default Address acknowledged if ENARP=1 and SMBTYPE=0
- SMB Host Header acknowledged if ENARP=1 and SMBTYPE=1
- SMB Alert Response Address acknowledged if SMBALERT=1

### 27.3.8 DMA requests

DMA requests (when enabled) are generated only for data transfer. DMA requests are generated by Data register becoming empty in transmission and Data register becoming full in reception. The DMA must be initialized and enabled before the I2C data transfer. The DMAEN bit must be set in the I2C\_CR2 register before the ADDR event. In master mode or in slave mode when clock stretching is enabled, the DMAEN bit can also be set during the ADDR event, before clearing the ADDR flag. The DMA request must be served before the end of the current byte transfer. When the number of data transfers which has been programmed for the corresponding DMA stream is reached, the DMA controller sends an End of Transfer EOT signal to the I<sup>2</sup>C interface and generates a Transfer Complete interrupt if enabled:

- Master transmitter: In the interrupt routine after the EOT interrupt, disable DMA requests then wait for a BTF event before programming the Stop condition.
- Master receiver
  - When the number of bytes to be received is equal to or greater than two, the DMA controller sends a hardware signal, EOT\_1, corresponding to the last but one data byte (number\_of\_bytes – 1). If, in the I2C\_CR2 register, the LAST bit is set, I<sup>2</sup>C automatically sends a NACK after the next byte following EOT\_1. The user can generate a Stop condition in the DMA Transfer Complete interrupt routine if enabled.
  - When a single byte must be received: the NACK must be programmed during EV6 event, i.e. program ACK=0 when ADDR=1, before clearing ADDR flag. Then the user can program the STOP condition either after clearing ADDR flag, or in the DMA Transfer Complete interrupt routine.

#### Transmission using DMA

DMA mode can be enabled for transmission by setting the DMAEN bit in the I2C\_CR2 register. Data are loaded from a Memory area configured using the DMA peripheral (refer to the DMA specification) to the I2C\_DR register whenever the TxE bit is set. To map a DMA stream x for I<sup>2</sup>C transmission (where x is the stream number), perform the following sequence:

1. Set the I2C\_DR register address in the DMA\_SxPAR register. The data are moved to this address from the memory after each TxE event.
2. Set the memory address in the DMA\_SxMA0R register (and in DMA\_SxMA1R register in the case of a double buffer mode). The data are loaded into I2C\_DR from this memory after each TxE event.
3. Configure the total number of bytes to be transferred in the DMA\_SxNDTR register. After each TxE event, this value is decremented.
4. Configure the DMA stream priority using the PL[0:1] bits in the DMA\_SxCR register.
5. Set the DIR bit in the DMA\_SxCR register and configure interrupts after half transfer or full transfer depending on application requirements.
6. Activate the stream by setting the EN bit in the DMA\_SxCR register.

When the number of data transfers which has been programmed in the DMA Controller registers is reached, the DMA controller sends an End of Transfer EOT/ EOT\_1 signal to the I<sup>2</sup>C interface and the DMA generates an interrupt, if enabled, on the DMA stream interrupt vector.

*Note:* Do not enable the ITBUFEN bit in the I2C\_CR2 register if DMA is used for transmission.

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAEN bit in the I2C\_CR2 register. Data are loaded from the I2C\_DR register to a Memory area configured using the DMA peripheral (refer to the DMA specification) whenever a data byte is received. To map a DMA stream x for I<sup>2</sup>C reception (where x is the stream number), perform the following sequence:

1. Set the I2C\_DR register address in DMA\_SxPAR register. The data are moved from this address to the memory after each RxNE event.
2. Set the memory address in the DMA\_SxMA0R register (and in DMA\_SxMA1R register in the case of a double buffer mode). The data are loaded from the I2C\_DR register to this memory area after each RxNE event.
3. Configure the total number of bytes to be transferred in the DMA\_SxNDTR register. After each RxNE event, this value is decremented.
4. Configure the stream priority using the PL[0:1] bits in the DMA\_SxCR register
5. Reset the DIR bit and configure interrupts in the DMA\_SxCR register after half transfer or full transfer depending on application requirements.
6. Activate the stream by setting the EN bit in the DMA\_SxCR register.

When the number of data transfers which has been programmed in the DMA Controller registers is reached, the DMA controller sends an End of Transfer EOT/ EOT\_1 signal to the I<sup>2</sup>C interface and DMA generates an interrupt, if enabled, on the DMA stream interrupt vector.

*Note:* Do not enable the ITBUFEN bit in the I2C\_CR2 register if DMA is used for reception.

### 27.3.9 Packet error checking

A PEC calculator has been implemented to improve the reliability of communication. The PEC is calculated by using the  $C(x) = x^8 + x^2 + x + 1$  CRC-8 polynomial serially on each bit.

- PEC calculation is enabled by setting the ENPEC bit in the I2C\_CR1 register. PEC is a CRC-8 calculated on all message bytes including addresses and R/W bits.
  - In transmission: set the PEC transfer bit in the I2C\_CR1 register after the TxE event corresponding to the last byte. The PEC is transferred after the last transmitted byte.
  - In reception: set the PEC bit in the I2C\_CR1 register after the RxNE event corresponding to the last byte so that the receiver sends a NACK if the next received byte is not equal to the internally calculated PEC. In case of Master-Receiver, a NACK must follow the PEC whatever the check result. The PEC must

be set before the ACK of the CRC reception in slave mode. It must be set when the ACK is set low in master mode.

- A PECERR error flag/interrupt is also available in the I2C\_SR1 register.
- If DMA and PEC calculation are both enabled:-
  - In transmission: when the I<sup>2</sup>C interface receives an EOT signal from the DMA controller, it automatically sends a PEC after the last byte.
  - In reception: when the I<sup>2</sup>C interface receives an EOT\_1 signal from the DMA controller, it automatically considers the next byte as a PEC and checks it. A DMA request is generated after PEC reception.
- To allow intermediate PEC transfers, a control bit is available in the I2C\_CR2 register (LAST bit) to determine if it is really the last DMA transfer or not. If it is the last DMA request for a master receiver, a NACK is automatically sent after the last received byte.
- PEC calculation is corrupted by an arbitration loss.

## 27.4 I<sup>2</sup>C interrupts

The table below gives the list of I<sup>2</sup>C interrupt requests.

**Table 125. I<sup>2</sup>C Interrupt requests**

| Interrupt event                                  | Event flag | Enable control bit  |
|--------------------------------------------------|------------|---------------------|
| Start bit sent (Master)                          | SB         | ITEVFEN             |
| Address sent (Master) or Address matched (Slave) | ADDR       |                     |
| 10-bit header sent (Master)                      | ADD10      |                     |
| Stop received (Slave)                            | STOPF      |                     |
| Data byte transfer finished                      | BTF        |                     |
| Receive buffer not empty                         | RxNE       | ITEVFEN and ITBUFEN |
| Transmit buffer empty                            | TxE        |                     |
| Bus error                                        | BERR       | ITERREN             |
| Arbitration loss (Master)                        | ARLO       |                     |
| Acknowledge failure                              | AF         |                     |
| Overrun/Underrun                                 | OVR        |                     |
| PEC error                                        | PECERR     |                     |
| Timeout/Tlow error                               | TIMEOUT    |                     |
| SMBus Alert                                      | SMBALERT   |                     |

*Note:* SB, ADDR, ADD10, STOPF, BTF, RxNE and TxE are logically OR-ed on the same interrupt channel.

BERR, ARLO, AF, OVR, PECERR, TIMEOUT and SMBALERT are logically OR-ed on the same interrupt channel.

Figure 245. I<sup>2</sup>C interrupt mapping diagram

## 27.5 I<sup>2</sup>C debug mode

When the microcontroller enters the debug mode (Cortex<sup>®</sup>-M4 with FPU core halted), the SMBUS timeout either continues to work normally or stops, depending on the DBG\_I2Cx\_SMBUS\_TIMEOUT configuration bits in the DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

## 27.6 I<sup>2</sup>C registers

Refer to [Section 1.1](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by half-words (16 bits) or words (32 bits).

### 27.6.1 I<sup>2</sup>C Control register 1 (I2C\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15    | 14   | 13    | 12  | 11  | 10  | 9    | 8     | 7          | 6   | 5     | 4     | 3        | 2    | 1     | 0  |
|-------|------|-------|-----|-----|-----|------|-------|------------|-----|-------|-------|----------|------|-------|----|
| SWRST | Res. | ALERT | PEC | POS | ACK | STOP | START | NO STRETCH | ENG | ENPEC | ENARP | SMB TYPE | Res. | SMBUS | PE |
| rw    |      | rw    | rw  | rw  | rw  | rw   | rw    | rw         | rw  | rw    | rw    | rw       |      | rw    | rw |

Bit 15 **SWRST**: Software reset

When set, the I2C is under reset state. Before resetting this bit, make sure the I2C lines are released and the bus is free.

0: I<sup>2</sup>C Peripheral not under reset

1: I<sup>2</sup>C Peripheral under reset state

*Note: This bit can be used to reinitialize the peripheral after an error or a locked state. As an example, if the BUSY bit is set and remains locked due to a glitch on the bus, the SWRST bit can be used to exit from this state.*

Bit 14 Reserved, must be kept at reset value

Bit 13 **ALERT**: SMBus alert

This bit is set and cleared by software, and cleared by hardware when PE=0.

0: Releases SMBA pin high. Alert Response Address Header followed by NACK.

1: Drives SMBA pin low. Alert Response Address Header followed by ACK.

Bit 12 **PEC**: Packet error checking

This bit is set and cleared by software, and cleared by hardware when PEC is transferred or by a START or Stop condition or when PE=0.

0: No PEC transfer

1: PEC transfer (in Tx or Rx mode)

*Note: PEC calculation is corrupted by an arbitration loss.*

Bit 11 **POS**: Acknowledge/PEC Position (for data reception)

This bit is set and cleared by software and cleared by hardware when PE=0.

0: ACK bit controls the (N)ACK of the current byte being received in the shift register. The PEC bit indicates that current byte in shift register is a PEC.

1: ACK bit controls the (N)ACK of the next byte which is received in the shift register. The PEC bit indicates that the next byte in the shift register is a PEC

*Note: The POS bit must be used only in 2-byte reception configuration in master mode. It must be configured before data reception starts, as described in the 2-byte reception procedure recommended in [Section : Master receiver on page 852](#).*

Bit 10 **ACK**: Acknowledge enable

This bit is set and cleared by software and cleared by hardware when PE=0.

0: No acknowledge returned

1: Acknowledge returned after a byte is received (matched address or data)

Bit 9 **STOP**: Stop generation

The bit is set and cleared by software, cleared by hardware when a Stop condition is detected, set by hardware when a timeout error is detected.

In Master mode:

0: No Stop generation.

1: Stop generation after the current byte transfer or after the current Start condition is sent.

In Slave mode:

0: No Stop generation.

1: Release the SCL and SDA lines after the current byte transfer.

Bit 8 **START**: Start generation

This bit is set and cleared by software and cleared by hardware when start is sent or PE=0.

In Master mode:

0: No Start generation

1: Repeated start generation

In Slave mode:

0: No Start generation

1: Start generation when the bus is free

Bit 7 **NOSTRETCH**: Clock stretching disable (Slave mode)

This bit is used to disable clock stretching in slave mode when ADDR or BTF flag is set, until it is reset by software.

0: Clock stretching enabled

1: Clock stretching disabled

Bit 6 **ENGCG**: General call enable

0: General call disabled. Address 00h is NACKed.

1: General call enabled. Address 00h is ACKed.

Bit 5 **ENPEC**: PEC enable

0: PEC calculation disabled

1: PEC calculation enabled

Bit 4 **ENARP**: ARP enable

0: ARP disable

1: ARP enable

SMBus Device default address recognized if SMBTYPE=0

SMBus Host address recognized if SMBTYPE=1

Bit 3 **SMBTYPE**: SMBus type

0: SMBus Device

1: SMBus Host

Bit 2 Reserved, must be kept at reset value

Bit 1 **SMBUS**: SMBus mode

0: I<sup>2</sup>C mode

1: SMBus mode

Bit 0 **PE**: Peripheral enable

0: Peripheral disable

1: Peripheral enable

*Note: If this bit is reset while a communication is on going, the peripheral is disabled at the end of the current communication, when back to IDLE state.*

*All bit resets due to PE=0 occur at the end of the communication.*

*In master mode, this bit must not be reset before the end of the communication.*

*Note: When the STOP, START or PEC bit is set, the software must not perform any write access to I2C\_CR1 before this bit is cleared by hardware. Otherwise there is a risk of setting a second STOP, START or PEC request.*

## 27.6.2 I<sup>2</sup>C Control register 2 (I2C\_CR2)

Address offset: 0x04

Reset value: 0x0000

| 15       | 14 | 13 | 12   | 11    | 10      | 9       | 8       | 7        | 6 | 5         | 4  | 3  | 2  | 1  | 0  |
|----------|----|----|------|-------|---------|---------|---------|----------|---|-----------|----|----|----|----|----|
| Reserved |    |    | LAST | DMAEN | ITBUFEN | ITEVTEN | ITERREN | Reserved |   | FREQ[5:0] |    |    |    |    |    |
|          |    |    | rw   | rw    | rw      | rw      | rw      |          |   | rw        | rw | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value

Bit 12 **LAST**: DMA last transfer

0: Next DMA EOT is not the last transfer

1: Next DMA EOT is the last transfer

*Note: This bit is used in master receiver mode to permit the generation of a NACK on the last received data.*

Bit 11 **DMAEN**: DMA requests enable

0: DMA requests disabled

1: DMA request enabled when TxNE=1 or RxNE =1

Bit 10 **ITBUFEN**: Buffer interrupt enable

0: TxNE = 1 or RxNE = 1 does not generate any interrupt.

1: TxNE = 1 or RxNE = 1 generates Event Interrupt (whatever the state of DMAEN)

Bit 9 **ITEVTEN**: Event interrupt enable

0: Event interrupt disabled

1: Event interrupt enabled

This interrupt is generated when:

- SB = 1 (Master)
- ADDR = 1 (Master/Slave)
- ADD10 = 1 (Master)
- STOPF = 1 (Slave)
- BTF = 1 with no TxE or RxNE event
- TxE event to 1 if ITBUFEN = 1
- RxNE event to 1 if ITBUFEN = 1

Bit 8 **ITERREN**: Error interrupt enable

0: Error interrupt disabled

1: Error interrupt enabled

This interrupt is generated when:

- BERR = 1
- ARLO = 1
- AF = 1
- OVR = 1
- PECERR = 1
- TIMEOUT = 1
- SMBALERT = 1

Bits 7:6 Reserved, must be kept at reset value

Bits 5:0 **FREQ[5:0]**: Peripheral clock frequency

The FREQ bits must be configured with the APB clock frequency value (I2C peripheral connected to APB). The FREQ field is used by the peripheral to generate data setup and hold times compliant with the I2C specifications. The minimum allowed frequency is 2 MHz, the maximum frequency is limited by the maximum APB frequency and cannot exceed 50 MHz (peripheral intrinsic maximum limit).

0b000000: Not allowed

0b000001: Not allowed

0b000010: 2 MHz

...

0b110010: 50 MHz

Higher than 0b101010: Not allowed

### 27.6.3 I<sup>2</sup>C Own address register 1 (I2C\_OAR1)

Address offset: 0x08

Reset value: 0x0000

| 15          | 14       | 13 | 12 | 11 | 10 | 9        | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0    |
|-------------|----------|----|----|----|----|----------|----|----------|----|----|----|----|----|----|------|
| ADD<br>MODE | Reserved |    |    |    |    | ADD[9:8] |    | ADD[7:1] |    |    |    |    |    |    | ADD0 |
| rw          |          |    |    |    |    | rw       | rw | rw       | rw | rw | rw | rw | rw | rw | rw   |

Bit 15 **ADDMODE** Addressing mode (slave mode)

0: 7-bit slave address (10-bit address not acknowledged)

1: 10-bit slave address (7-bit address not acknowledged)

Bit 14 Should always be kept at 1 by software.

Bits 13:10 Reserved, must be kept at reset value

Bits 9:8 **ADD[9:8]**: Interface address

7-bit addressing mode: don't care

10-bit addressing mode: bits9:8 of address

Bits 7:1 **ADD[7:1]**: Interface address

bits 7:1 of address

Bit 0 **ADD0**: Interface address

7-bit addressing mode: don't care

10-bit addressing mode: bit 0 of address

### 27.6.4 I<sup>2</sup>C Own address register 2 (I2C\_OAR2)

Address offset: 0x0C

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0      |
|----------|----|----|----|----|----|---|---|-----------|----|----|----|----|----|----|--------|
| Reserved |    |    |    |    |    |   |   | ADD2[7:1] |    |    |    |    |    |    | ENDUAL |
|          |    |    |    |    |    |   |   | rw        | rw | rw | rw | rw | rw | rw | rw     |

Bits 15:8 Reserved, must be kept at reset value

Bits 7:1 **ADD2[7:1]**: Interface address

bits 7:1 of address in dual addressing mode

Bit 0 **ENDUAL**: Dual addressing mode enable

0: Only OAR1 is recognized in 7-bit addressing mode

1: Both OAR1 and OAR2 are recognized in 7-bit addressing mode

### 27.6.5 I<sup>2</sup>C Data register (I2C\_DR)

Address offset: 0x10

Reset value: 0x0000

|          |    |    |    |    |    |   |   |         |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|---|---|---------|----|----|----|----|----|----|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7       | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |   |   | DR[7:0] |    |    |    |    |    |    |    |
|          |    |    |    |    |    |   |   | rw      | rw | rw | rw | rw | rw | rw | rw |

Bits 15:8 Reserved, must be kept at reset value

Bits 7:0 **DR[7:0]** 8-bit data register

Byte received or to be transmitted to the bus.

- Transmitter mode: Byte transmission starts automatically when a byte is written in the DR register. A continuous transmit stream can be maintained if the next data to be transmitted is put in DR once the transmission is started (TxNE=1)
- Receiver mode: Received byte is copied into DR (RxNE=1). A continuous transmit stream can be maintained if DR is read before the next data byte is received (RxNE=1).

*Note: In slave mode, the address is not copied into DR.**Write collision is not managed (DR can be written if TxNE=0).**If an ARLO event occurs on ACK pulse, the received byte is not copied into DR and so cannot be read.*

### 27.6.6 I<sup>2</sup>C Status register 1 (I2C\_SR1)

Address offset: 0x14

Reset value: 0x0000

|              |             |      |            |       |       |       |       |     |      |      |       |       |     |      |    |
|--------------|-------------|------|------------|-------|-------|-------|-------|-----|------|------|-------|-------|-----|------|----|
| 15           | 14          | 13   | 12         | 11    | 10    | 9     | 8     | 7   | 6    | 5    | 4     | 3     | 2   | 1    | 0  |
| SMB<br>ALERT | TIME<br>OUT | Res. | PEC<br>ERR | OVR   | AF    | ARLO  | BERR  | TxE | RxNE | Res. | STOPF | ADD10 | BTF | ADDR | SB |
| rc_w0        | rc_w0       |      | rc_w0      | rc_w0 | rc_w0 | rc_w0 | rc_w0 | r   | r    |      | r     | r     | r   | r    | r  |

Bit 15 **SMBALERT**: SMBus alert

In SMBus host mode:

0: no SMBALERT

1: SMBALERT event occurred on pin

In SMBus slave mode:

0: no SMBALERT response address header

1: SMBALERT response address header to SMBALERT LOW received

- Cleared by software writing 0, or by hardware when PE=0.

Bit 14 **TIMEOUT**: Timeout or Tlow error

0: No timeout error

1: SCL remained LOW for 25 ms (Timeout)

or

Master cumulative clock low extend time more than 10 ms (Tlow:mext)

or

Slave cumulative clock low extend time more than 25 ms (Tlow:sext)

- When set in slave mode: slave resets the communication and lines are released by hardware
- When set in master mode: Stop condition sent by hardware
- Cleared by software writing 0, or by hardware when PE=0.

*Note: This functionality is available only in SMBus mode.*

## Bit 13 Reserved, must be kept at reset value

Bit 12 **PECERR**: PEC Error in reception

0: no PEC error: receiver returns ACK after PEC reception (if ACK=1)

1: PEC error: receiver returns NACK after PEC reception (whatever ACK)

- Cleared by software writing 0, or by hardware when PE=0.

*Note: When the received CRC is wrong, PECERR is not set in slave mode if the PEC control bit is not set before the end of the CRC reception. Nevertheless, reading the PEC value determines whether the received CRC is right or wrong.*

Bit 11 **OVR**: Overrun/Underrun

0: No overrun/underrun

1: Overrun or underrun

- Set by hardware in slave mode when NOSTRETCH=1 and:
- In reception when a new byte is received (including ACK pulse) and the DR register has not been read yet. New received byte is lost.
- In transmission when a new byte should be sent and the DR register has not been written yet. The same byte is sent twice.
- Cleared by software writing 0, or by hardware when PE=0.

*Note: If the DR write occurs very close to SCL rising edge, the sent data is unspecified and a hold timing error occurs*

Bit 10 **AF**: Acknowledge failure

0: No acknowledge failure

1: Acknowledge failure

- Set by hardware when no acknowledge is returned.
- Cleared by software writing 0, or by hardware when PE=0.

Bit 9 **ARLO**: Arbitration lost (master mode)

0: No Arbitration Lost detected

1: Arbitration Lost detected

Set by hardware when the interface loses the arbitration of the bus to another master

- Cleared by software writing 0, or by hardware when PE=0.

After an ARLO event the interface switches back automatically to Slave mode (MSL=0).

*Note: In SMBUS, the arbitration on the data in slave mode occurs only during the data phase, or the acknowledge transmission (not on the address acknowledge).*

Bit 8 **BERR**: Bus error

- 0: No misplaced Start or Stop condition
- 1: Misplaced Start or Stop condition

- Set by hardware when the interface detects an SDA rising or falling edge while SCL is high, occurring in a non-valid position during a byte transfer.
- Cleared by software writing 0, or by hardware when PE=0.

Bit 7 **TxE**: Data register empty (transmitters)

- 0: Data register not empty
- 1: Data register empty

- Set when DR is empty in transmission. TxE is not set during address phase.
- Cleared by software writing to the DR register or by hardware after a start or a stop condition or when PE=0.

TxE is not set if either a NACK is received, or if next byte to be transmitted is PEC (PEC=1)

*Note: TxE is not cleared by writing the first data being transmitted, or by writing data when BTF is set, as in both cases the data register is still empty.*

Bit 6 **RxNE**: Data register not empty (receivers)

- 0: Data register empty
- 1: Data register not empty

- Set when data register is not empty in receiver mode. RxNE is not set during address phase.
- Cleared by software reading or writing the DR register or by hardware when PE=0.

RxNE is not set in case of ARLO event.

*Note: RxNE is not cleared by reading data when BTF is set, as the data register is still full.*

## Bit 5 Reserved, must be kept at reset value

Bit 4 **STOPF**: Stop detection (slave mode)

- 0: No Stop condition detected
- 1: Stop condition detected

- Set by hardware when a Stop condition is detected on the bus by the slave after an acknowledge (if ACK=1).
- Cleared by software reading the SR1 register followed by a write in the CR1 register, or by hardware when PE=0

*Note: The STOPF bit is not set after a NACK reception.*

*It is recommended to perform the complete clearing sequence (READ SR1 then WRITE CR1) after the STOPF is set. Refer to [Figure 242](#).*

Bit 3 **ADD10**: 10-bit header sent (Master mode)

- 0: No ADD10 event occurred.
- 1: Master has sent first address byte (header).

- Set by hardware when the master has sent the first byte in 10-bit address mode.
- Cleared by software reading the SR1 register followed by a write in the DR register of the second address byte, or by hardware when PE=0.

*Note: ADD10 bit is not set after a NACK reception*

**Bit 2 BTF:** Byte transfer finished

0: Data byte transfer not done

1: Data byte transfer succeeded

- Set by hardware when NOSTRETCH=0 and:
- In reception when a new byte is received (including ACK pulse) and DR has not been read yet (RxNE=1).
- In transmission when a new byte should be sent and DR has not been written yet (TxE=1).
- Cleared by software by either a read or write in the DR register or by hardware after a start or a stop condition in transmission or when PE=0.

*Note: The BTF bit is not set after a NACK reception*

*The BTF bit is not set if next byte to be transmitted is the PEC (TRA=1 in I2C\_SR2 register and PEC=1 in I2C\_CR1 register)*

**Bit 1 ADDR:** Address sent (master mode)/matched (slave mode)

This bit is cleared by software reading SR1 register followed reading SR2, or by hardware when PE=0.

Address matched (Slave)

0: Address mismatched or not received.

1: Received address matched.

- Set by hardware as soon as the received slave address matched with the OAR registers content or a general call or a SMBus Device Default Address or SMBus Host or SMBus Alert is recognized. (when enabled depending on configuration).

*Note: In slave mode, it is recommended to perform the complete clearing sequence (READ SR1 then READ SR2) after ADDR is set. Refer to [Figure 242](#).*

Address sent (Master)

0: No end of address transmission

1: End of address transmission

- For 10-bit addressing, the bit is set after the ACK of the 2nd byte.
- For 7-bit addressing, the bit is set after the ACK of the byte.

*Note: ADDR is not set after a NACK reception***Bit 0 SB:** Start bit (Master mode)

0: No Start condition

1: Start condition generated.

- Set when a Start condition generated.
- Cleared by software by reading the SR1 register followed by writing the DR register, or by hardware when PE=0

**27.6.7 I<sup>2</sup>C Status register 2 (I2C\_SR2)**

Address offset: 0x18

Reset value: 0x0000

*Note: Reading I2C\_SR2 after reading I2C\_SR1 clears the ADDR flag, even if the ADDR flag was set after reading I2C\_SR1. Consequently, I2C\_SR2 must be read only when ADDR is found set in I2C\_SR1 or when the STOPF bit is cleared.*

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6        | 5           | 4        | 3    | 2   | 1    | 0   |
|----------|----|----|----|----|----|---|---|-------|----------|-------------|----------|------|-----|------|-----|
| PEC[7:0] |    |    |    |    |    |   |   | DUALF | SMB HOST | SMBDE FAULT | GEN CALL | Res. | TRA | BUSY | MSL |
| r        | r  | r  | r  | r  | r  | r | r | r     | r        | r           | r        |      | r   | r    | r   |

Bits 15:8 **PEC[7:0]** Packet error checking register

This register contains the internal PEC when ENPEC=1.

Bit 7 **DUALF**: Dual flag (Slave mode)

0: Received address matched with OAR1

1: Received address matched with OAR2

– Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 6 **SMBHOST**: SMBus host header (Slave mode)

0: No SMBus Host address

1: SMBus Host address received when SMBTYPE=1 and ENARP=1.

– Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 5 **SMBDEFAULT**: SMBus device default address (Slave mode)

0: No SMBus Device Default address

1: SMBus Device Default address received when ENARP=1

– Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 4 **GENCALL**: General call address (Slave mode)

0: No General Call

1: General Call Address received when ENGC=1

– Cleared by hardware after a Stop condition or repeated Start condition, or when PE=0.

Bit 3 Reserved, must be kept at reset value

Bit 2 **TRA**: Transmitter/receiver

0: Data bytes received

1: Data bytes transmitted

This bit is set depending on the R/W bit of the address byte, at the end of total address phase.

It is also cleared by hardware after detection of Stop condition (STOPF=1), repeated Start condition, loss of bus arbitration (ARLO=1), or when PE=0.

Bit 1 **BUSY**: Bus busy

0: No communication on the bus

1: Communication ongoing on the bus

– Set by hardware on detection of SDA or SCL low

– cleared by hardware on detection of a Stop condition.

It indicates a communication in progress on the bus. This information is still updated when the interface is disabled (PE=0).

Bit 0 **MSL**: Master/slave

0: Slave mode

1: Master mode

– Set by hardware as soon as the interface is in Master mode (SB=1).

– Cleared by hardware after detecting a Stop condition on the bus or a loss of arbitration (ARLO=1), or by hardware when PE=0.

**Note:** Reading I2C\_SR2 after reading I2C\_SR1 clears the ADDR flag, even if the ADDR flag was set after reading I2C\_SR1. Consequently, I2C\_SR2 must be read only when ADDR is found set in I2C\_SR1 or when the STOPF bit is cleared.

## 27.6.8 I<sup>2</sup>C Clock control register (I2C\_CCR)

Address offset: 0x1C

Reset value: 0x0000

**Note:**  $f_{PCLK1}$  must be at least 2 MHz to achieve Sm mode I<sup>2</sup>C frequencies. It must be at least 4 MHz to achieve Fm mode I<sup>2</sup>C frequencies. It must be a multiple of 10MHz to reach the 400 kHz maximum I<sup>2</sup>C Fm mode clock.

The CCR register must be configured only when the I2C is disabled (PE = 0).

| 15  | 14   | 13       | 12 | 11        | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|-----|------|----------|----|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| F/S | DUTY | Reserved |    | CCR[11:0] |     |     |     |     |     |     |     |     |     |     |     |
| r/w | r/w  |          |    | r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bit 15 **F/S**: I2C master mode selection

0: Sm mode I2C

1: Fm mode I2C

Bit 14 **DUTY**: Fm mode duty cycle

0: Fm mode  $t_{low}/t_{high} = 2$

1: Fm mode  $t_{low}/t_{high} = 16/9$  (see CCR)

Bits 13:12 Reserved, must be kept at reset value

Bits 11:0 **CCR[11:0]**: Clock control register in Fm/Sm mode (Master mode)

Controls the SCL clock in master mode.

Sm mode or SMBus:

$$T_{high} = CCR * T_{PCLK1}$$

$$T_{low} = CCR * T_{PCLK1}$$

Fm mode:

If DUTY = 0:

$$T_{high} = CCR * T_{PCLK1}$$

$$T_{low} = 2 * CCR * T_{PCLK1}$$

If DUTY = 1:

$$T_{high} = 9 * CCR * T_{PCLK1}$$

$$T_{low} = 16 * CCR * T_{PCLK1}$$

For instance: in Sm mode, to generate a 100 kHz SCL frequency:

If  $FREQ = 08$ ,  $T_{PCLK1} = 125$  ns so CCR must be programmed with 0x28

( $0x28 \Leftrightarrow 40d \times 125$  ns = 5000 ns.)

**Note:** The minimum allowed value is 0x04, except in FAST DUTY mode where the minimum allowed value is 0x01

$$t_{high} = t_{r(SCL)} + t_{w(SCLH)}$$

$$t_{low} = t_{f(SCL)} + t_{w(SCLL)}$$

Where the I2C parameters below are part of the I2C standard specification.

-  $t_{r(SCL)}$  = SCL clock rise time from 30% to 70%.

-  $t_{f(SCL)}$  = SCL clock fall time from 70% to 30%.

-  $t_{w(SCLH)}$  = SCL clock high time measure at 70%.

-  $t_{w(SCLL)}$  = SCL clock low time measure at 30%.

I2C communication speed,  $f_{SCL} \sim 1/(t_{high} + t_{low})$ . The real frequency may differ due to the analog noise filter input delay.

The CCR register must be configured only when the I<sup>2</sup>C is disabled (PE = 0).

### 27.6.9 I<sup>2</sup>C TRISE register (I2C\_TRISE)

Address offset: 0x20

Reset value: 0x0002

|          |    |    |    |    |    |   |   |   |   |            |    |    |    |    |    |
|----------|----|----|----|----|----|---|---|---|---|------------|----|----|----|----|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5          | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |   |   |   |   | TRISE[5:0] |    |    |    |    |    |
|          |    |    |    |    |    |   |   |   |   | rw         | rw | rw | rw | rw | rw |

Bits 15:6 Reserved, must be kept at reset value

Bits 5:0 **TRISE[5:0]**: Maximum rise time in Fm/Sm mode (Master mode)

These bits should provide the maximum duration of the SCL feedback loop in master mode. The purpose is to keep a stable SCL frequency whatever the SCL rising edge duration.

These bits must be programmed with the maximum SCL rise time given in the I<sup>2</sup>C bus specification, incremented by 1.

For instance: in Sm mode, the maximum allowed SCL rise time is 1000 ns.

If, in the I2C\_CR2 register, the value of FREQ[5:0] bits is equal to 0x08 and T<sub>PCLK1</sub> = 125 ns therefore the TRISE[5:0] bits must be programmed with 09h.

(1000 ns / 125 ns = 8 + 1)

The filter value can also be added to TRISE[5:0].

If the result is not an integer, TRISE[5:0] must be programmed with the integer part, in order to respect the t<sub>HIGH</sub> parameter.

*Note: TRISE[5:0] must be configured only when the I2C is disabled (PE = 0).*

### 27.6.10 I<sup>2</sup>C FLTR register (I2C\_FLTR)

Address offset: 0x24

Reset value: 0x0000

The I2C\_FLTR is available on STM32F42xxx and STM32F43xxx only.

|          |    |    |    |    |    |   |   |   |   |       |          |    |    |    |    |
|----------|----|----|----|----|----|---|---|---|---|-------|----------|----|----|----|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5     | 4        | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |   |   |   |   | ANOFF | DNF[3:0] |    |    |    |    |
|          |    |    |    |    |    |   |   |   |   | rw    | rw       | rw | rw | rw | rw |

Bits 15:5 Reserved, must be kept at reset value

Bit 4 **ANOFF**: Analog noise filter OFF

0: Analog noise filter enable

1: Analog noise filter disable

*Note: ANOFF must be configured only when the I2C is disabled (PE = 0).*

Bits 3:0 **DNF[3:0]**: Digital noise filter

These bits are used to configure the digital noise filter on SDA and SCL inputs. The digital filter suppresses the spikes with a length of up to DNF[3:0] \* TPCLK1.

0000: Digital noise filter disable

0001: Digital noise filter enabled and filtering capability up to 1\* TPCLK1.

...

1111: Digital noise filter enabled and filtering capability up to 15\* TPCLK1.

*Note: DNF[3:0] must be configured only when the I2C is disabled (PE = 0). If the analog filter is also enabled, the digital filter is added to the analog filter.*

The table below provides the I<sup>2</sup>C register map and reset values.

### Table 126. I<sup>2</sup>C register map and reset values

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14       | 13       | 12        | 11    | 10       | 9         | 8        | 7          | 6         | 5          | 4     | 3       | 2        | 1     | 0  |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses table.

## 28 Serial peripheral interface (SPI)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 28.1 SPI introduction

The SPI interface provides two main functions, supporting the SPI or the I<sup>2</sup>S audio protocol. By default, the SPI function is selected. It is possible to switch the interface from SPI to I<sup>2</sup>S by software.

The serial peripheral interface (SPI) allows half/ full-duplex, synchronous, serial communication with external devices. The interface can be configured as the master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

It may be used for a variety of purposes, including simplex synchronous transfers on two lines with a possible bidirectional data line or reliable communication using CRC checking.

The I<sup>2</sup>S is also a synchronous serial communication interface. It can address four different audio standards including the I<sup>2</sup>S Philips standard, the MSB- and LSB-justified standards, and the PCM standard. It can operate as a slave or a master device in full-duplex mode (using 4 pins) or in half-duplex mode (using 3 pins). Master clock can be provided by the interface to an external slave component when the I<sup>2</sup>S is configured as the communication master.

---

**Warning:** Since some SPI1 and SPI3/I2S3 pins may be mapped onto some pins used by the JTAG interface (SPI1\_NSS onto JTDI, SPI3\_NSS/I2S3\_WS onto JTDI and SPI3\_SCK/I2S3\_CK onto JTDO), you may either:

- map SPI/I2S onto other pins
- disable the JTAG and use the SWD interface prior to configuring the pins listed as SPI I/Os (when debugging the application) or
- disable both JTAG/SWD interfaces (for standalone applications).

For more information on the configuration of the JTAG/SWD interface pins, please refer to [Section 8.3.2: I/O pin multiplexer and mapping](#).

---

## 28.2 SPI and I<sup>2</sup>S main features

### 28.2.1 SPI features

- Full-duplex synchronous transfers on three lines
- Simplex synchronous transfers on two lines with or without a bidirectional data line
- 8- or 16-bit transfer frame format selection
- Master or slave operation
- Multimaster mode capability
- 8 master mode baud rate prescalers ( $f_{PCLK}/2$  max.)
- Slave mode frequency ( $f_{PCLK}/2$  max)
- Faster communication for both master and slave
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- SPI TI mode
- Hardware CRC feature for reliable communication:
  - CRC value can be transmitted as last byte in Tx mode
  - Automatic CRC error checking for last received byte
- Master mode fault, overrun and CRC error flags with interrupt capability
- 1-byte transmission and reception buffer with DMA capability: Tx and Rx requests

### 28.2.2 I<sup>2</sup>S features

- Full duplex communication
- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler to reach accurate audio sample frequencies (from 8 kHz to 192 kHz)
- Data format may be 16-bit, 24-bit or 32-bit
- Packet frame is fixed to 16-bit (16-bit data frame) or 32-bit (16-bit, 24-bit, 32-bit data frame) by audio channel
- Programmable clock polarity (steady state)
- Underrun flag in slave transmission mode, overrun flag in reception mode (master and slave), and Frame Error flag in reception and transmission mode (slave only)
- 16-bit register for transmission and reception with one data register for both channel sides
- Supported I<sup>2</sup>S protocols:
  - I<sup>2</sup>S Philips standard
  - MSB-justified standard (left-justified)
  - LSB-justified standard (right-justified)
  - PCM standard (with short and long frame synchronization on 16-bit channel frame or 16-bit data frame extended to 32-bit channel frame)
- Data direction is always MSB first
- DMA capability for transmission and reception (16-bit wide)
- Master clock may be output to drive an external audio component. Ratio is fixed at  $256 \times F_S$  (where  $F_S$  is the audio sampling frequency)
- Both I<sup>2</sup>S (I2S2 and I2S3) have a dedicated PLL (PLLI2S) to generate an even more accurate clock.
- I<sup>2</sup>S (I2S2 and I2S3) clock can be derived from an external clock mapped on the I2S\_CKIN pin.

## 28.3 SPI functional description

### 28.3.1 General description

The block diagram of the SPI is shown in [Figure 246](#).

Figure 246. SPI block diagram

Usually, the SPI is connected to external devices through four pins:

- **MISO:** Master In / Slave Out data. This pin can be used to transmit data in slave mode and receive data in master mode.
- **MOSI:** Master Out / Slave In data. This pin can be used to transmit data in master mode and receive data in slave mode.
- **SCK:** Serial Clock output for SPI masters and input for SPI slaves.
- **NSS:** Slave select. This is an optional pin to select a slave device. This pin acts as a 'chip select' to let the SPI master communicate with slaves individually and to avoid contention on the data lines. Slave NSS inputs can be driven by standard IO ports on the master device. The NSS pin may also be used as an output if enabled (SSOE bit) and driven low if the SPI is in master configuration. In this manner, all NSS pins from devices connected to the Master NSS pin see a low level and become slaves when they are configured in NSS hardware mode. When configured in master mode with NSS configured as an input (MSTR=1 and SSOE=0) and if NSS is pulled low, the SPI enters the master mode fault state: the MSTR bit is automatically cleared and the device is configured in slave mode (refer to [Section 28.3.10](#)).

A basic example of interconnections between a single master and a single slave is illustrated in [Figure 247](#).

**Figure 247. Single master/ single slave application**

1. Here, the NSS pin is configured as an input.

The MOSI pins are connected together and the MISO pins are connected together. In this way data is transferred serially between master and slave (most significant bit first).

The communication is always initiated by the master. When the master device transmits data to a slave device via the MOSI pin, the slave device responds via the MISO pin. This implies full-duplex communication with both data out and data in synchronized with the same clock signal (which is provided by the master device via the SCK pin).

### Slave select (NSS) pin management

Hardware or software slave select management can be set using the SSM bit in the SPI\_CR1 register.

- Software NSS management (SSM = 1)
 

The slave select information is driven internally by the value of the SSI bit in the SPI\_CR1 register. The external NSS pin remains free for other application uses.
- Hardware NSS management (SSM = 0)
 

Two configurations are possible depending on the NSS output configuration (SSOE bit in register SPI\_CR2).

  - NSS output enabled (SSM = 0, SSOE = 1)
 

This configuration is used only when the device operates in master mode. The NSS signal is driven low when the master starts the communication and is kept low until the SPI is disabled.
  - NSS output disabled (SSM = 0, SSOE = 0)
 

This configuration allows multimaster capability for devices operating in master mode. For devices set as slave, the NSS pin acts as a classical NSS input: the slave is selected when NSS is low and deselected when NSS high.

### Clock phase and clock polarity

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI\_CR1 register. The CPOL (clock polarity) bit controls the steady state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA (clock phase) bit is set, the second edge on the SCK pin (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set) is the MSBit capture strobe. Data are latched on the occurrence of the second clock transition. If the CPHA bit is reset, the first edge on the SCK pin (falling edge if CPOL bit is set, rising edge if CPOL bit is reset) is the MSBit capture strobe. Data are latched on the occurrence of the first clock transition.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.

[Figure 248](#), shows an SPI transfer with the four combinations of the CPHA and CPOL bits. The diagram may be interpreted as a master or slave timing diagram where the SCK pin, the MISO pin, the MOSI pin are directly connected between the master and the slave device.

**Note:** *Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit.  
Master and slave must be programmed with the same timing mode.  
The idle state of SCK must correspond to the polarity selected in the SPI\_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).  
The Data Frame Format (8- or 16-bit) is selected through the DFF bit in SPI\_CR1 register, and determines the data length during transmission/reception.*

Figure 248. Data clock timing diagram

1. These timings are shown with the LSBFIRST bit reset in the SPI\_CR1 register.

### Data frame format

Data can be shifted out either MSB-first or LSB-first depending on the value of the LSBFIRST bit in the SPI\_CR1 register.

Each data frame is 8 or 16 bits long depending on the size of the data programmed using the DFF bit in the SPI\_CR1 register. The selected data frame format is applicable for transmission and/or reception.

### 28.3.2 Configuring the SPI in slave mode

In the slave configuration, the serial clock is received on the SCK pin from the master device. The value set in the BR[2:0] bits in the SPI\_CR1 register, does not affect the data transfer rate.

*Note: It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication. It is mandatory to have the polarity of the communication clock set to the steady state value before the slave and the master are enabled.*

Follow the procedure below to configure the SPI in slave mode:

#### Procedure

1. Set the DFF bit to define 8- or 16-bit data frame format
2. Select the CPOL and CPHA bits to define one of the four relationships between the data transfer and the serial clock (see [Figure 248](#)). For correct data transfer, the CPOL and CPHA bits must be configured in the same way in the slave device and the master device. This step is not required when the TI mode is selected through the FRF bit in the SPI\_CR2 register.
3. The frame format (MSB-first or LSB-first depending on the value of the LSBFIRST bit in the SPI\_CR1 register) must be the same as the master device. This step is not required when TI mode is selected.
4. In Hardware mode (refer to [Slave select \(NSS\) pin management](#)), the NSS pin must be connected to a low level signal during the complete byte transmit sequence. In NSS software mode, set the SSM bit and clear the SSI bit in the SPI\_CR1 register. This step is not required when TI mode is selected.
5. Set the FRF bit in the SPI\_CR2 register to select the TI mode protocol for serial communications.
6. Clear the MSTR bit and set the SPE bit (both in the SPI\_CR1 register) to assign the pins to alternate functions.

In this configuration the MOSI pin is a data input and the MISO pin is a data output.

#### Transmit sequence

The data byte is parallel-loaded into the Tx buffer during a write cycle.

The transmit sequence begins when the slave device receives the clock signal and the most significant bit of the data on its MOSI pin. The remaining bits (the 7 bits in 8-bit data frame format, and the 15 bits in 16-bit data frame format) are loaded into the shift-register. The TXE flag in the SPI\_SR register is set on the transfer of data from the Tx Buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPI\_CR2 register is set.

#### Receive sequence

For the receiver, when data transfer is complete:

- The Data in shift register is transferred to Rx Buffer and the RXNE flag (SPI\_SR register) is set
- An Interrupt is generated if the RXNEIE bit is set in the SPI\_CR2 register.

After the last sampling clock edge the RXNE bit is set, a copy of the data byte received in the shift register is moved to the Rx buffer. When the SPI\_DR register is read, the SPI peripheral returns this buffered value.

Clearing of the RXNE bit is performed by reading the SPI\_DR register.

### SPI TI protocol in slave mode

In slave mode, the SPI interface is compatible with the TI protocol. The FRF bit of the SPI\_CR2 register can be used to configure the slave SPI serial communications to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPI\_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPI\_CR1 and SPI\_CR2 registers (such as SSM, SSI, SSOE) transparent for the user.

In Slave mode ([Figure 249: TI mode - Slave mode, single transfer](#) and [Figure 250: TI mode - Slave mode, continuous transfer](#)), the SPI baud rate prescaler is used to control the moment when the MISO pin state changes to HI-Z. Any baud rate can be used thus allowing to determine this moment with optimal flexibility. However, the baud rate is generally set to the external master clock baud rate. The time for the MISO signal to become HI-Z ( $t_{\text{release}}$ ) depends on internal resynchronizations and on the baud rate value set in through BR[2:0] of SPI\_CR1 register. It is given by the formula:

$$\frac{t_{\text{baud rate}}}{2} + 4 \times t_{\text{pclk}} < t_{\text{release}} < \frac{t_{\text{baud rate}}}{2} + 6 \times t_{\text{pclk}}$$

**Note:** This feature is not available for Motorola SPI communications (FRF bit set to 0).

To detect TI frame errors in Slave transmitter only mode by using the Error interrupt (ERRIE = 1), the SPI must be configured in 2-line unidirectional mode by setting BIDIMODE and BIDIOE to 1 in the SPI\_CR1 register. When BIDIMODE is set to 0, OVR is set to 1 because the data register is never read and error interrupt are always generated, while when BIDIMODE is set to 1, data are not received and OVR is never set.

**Figure 249. TI mode - Slave mode, single transfer**

Figure 250. TI mode - Slave mode, continuous transfer

### 28.3.3 Configuring the SPI in master mode

In the master configuration, the serial clock is generated on the SCK pin.

#### Procedure

1. Select the BR[2:0] bits to define the serial clock baud rate (see SPI\_CR1 register).
2. Select the CPOL and CPHA bits to define one of the four relationships between the data transfer and the serial clock (see [Figure 248](#)). This step is not required when the TI mode is selected.
3. Set the DFF bit to define 8- or 16-bit data frame format
4. Configure the LSBFIRST bit in the SPI\_CR1 register to define the frame format. This step is not required when the TI mode is selected.
5. If the NSS pin is required in input mode, in hardware mode, connect the NSS pin to a high-level signal during the complete byte transmit sequence. In NSS software mode, set the SSM and SSI bits in the SPI\_CR1 register. If the NSS pin is required in output mode, the SSOE bit only should be set. This step is not required when the TI mode is selected.
6. Set the FRF bit in SPI\_CR2 to select the TI protocol for serial communications.
7. The MSTR and SPE bits must be set (they remain set only if the NSS pin is connected to a high-level signal).

In this configuration the MOSI pin is a data output and the MISO pin is a data input.

#### Transmit sequence

The transmit sequence begins when a byte is written in the Tx Buffer.

The data byte is parallel-loaded into the shift register (from the internal bus) during the first bit transmission and then shifted out serially to the MOSI pin MSB first or LSB first depending on the LSBFIRST bit in the SPI\_CR1 register. The TXE flag is set on the transfer of data from the Tx Buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPI\_CR2 register is set.

### Receive sequence

For the receiver, when data transfer is complete:

- The data in the shift register is transferred to the RX Buffer and the RXNE flag is set
- An interrupt is generated if the RXNEIE bit is set in the SPI\_CR2 register

At the last sampling clock edge the RXNE bit is set, a copy of the data byte received in the shift register is moved to the Rx buffer. When the SPI\_DR register is read, the SPI peripheral returns this buffered value.

Clearing the RXNE bit is performed by reading the SPI\_DR register.

A continuous transmit stream can be maintained if the next data to be transmitted is put in the Tx buffer once the transmission is started. Note that TXE flag should be '1' before any attempt to write the Tx buffer is made.

**Note:** *When a master is communicating with SPI slaves which need to be de-selected between transmissions, the NSS pin must be configured as GPIO or another GPIO must be used and toggled by software.*

### SPI TI protocol in master mode

In master mode, the SPI interface is compatible with the TI protocol. The FRF bit of the SPI\_CR2 register can be used to configure the master SPI serial communications to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPI\_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPI\_CR1 and SPI\_CR2 registers (SSM, SSI, SSOE) transparent for the user.

*Figure 251: TI mode - master mode, single transfer and Figure 252: TI mode - master mode, continuous transfer* show the SPI master communication waveforms when the TI mode is selected in master mode.

**Figure 251. TI mode - master mode, single transfer**

Figure 252. TI mode - master mode, continuous transfer

### 28.3.4 Configuring the SPI for half-duplex communication

The SPI is capable of operating in half-duplex mode in 2 configurations.

- 1 clock and 1 bidirectional data wire
- 1 clock and 1 data wire (receive-only or transmit-only)

#### 1 clock and 1 bidirectional data wire (BIDIMODE = 1)

This mode is enabled by setting the BIDIMODE bit in the SPI\_CR1 register. In this mode SCK is used for the clock and MOSI in master or MISO in slave mode is used for data communication. The transfer direction (Input/Output) is selected by the BIDIOE bit in the SPI\_CR1 register. When this bit is 1, the data line is output otherwise it is input.

#### 1 clock and 1 unidirectional data wire (BIDIMODE = 0)

In this mode, the application can use the SPI either in transmit-only mode or in receive-only mode.

- Transmit-only mode is similar to full-duplex mode (BIDIMODE=0, RXONLY=0): the data are transmitted on the transmit pin (MOSI in master mode or MISO in slave mode) and the receive pin (MISO in master mode or MOSI in slave mode) can be used as a general-purpose IO. In this case, the application just needs to ignore the Rx buffer (if the data register is read, it does not contain the received value).
- In receive-only mode, the application can disable the SPI output function by setting the RXONLY bit in the SPI\_CR1 register. In this case, it frees the transmit IO pin (MOSI in master mode or MISO in slave mode), so it can be used for other purposes.

To start the communication in receive-only mode, configure and enable the SPI:

- In master mode, the communication starts immediately and stops when the SPE bit is cleared and the current reception stops. There is no need to read the BSY flag in this mode. It is always set when an SPI communication is ongoing.
- In slave mode, the SPI continues to receive as long as the NSS is pulled down (or the SSI bit is cleared in NSS software mode) and the SCK is running.

## 28.3.5 Data transmission and reception procedures

### Rx and Tx buffers

In reception, data are received and then stored into an internal Rx buffer while In transmission, data are first stored into an internal Tx buffer before being transmitted.

A read access of the SPI\_DR register returns the Rx buffered value whereas a write access to the SPI\_DR stores the written data into the Tx buffer.

### Start sequence in master mode

- In full-duplex (BIDIMODE=0 and RXONLY=0)
  - The sequence begins when data are written into the SPI\_DR register (Tx buffer).
  - The data are then parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission and then shifted out serially to the MOSI pin.
  - At the same time, the received data on the MISO pin is shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
- In unidirectional receive-only mode (BIDIMODE=0 and RXONLY=1)
  - The sequence begins as soon as SPE=1
  - Only the receiver is activated and the received data on the MISO pin are shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
- In bidirectional mode, when transmitting (BIDIMODE=1 and BIDIOE=1)
  - The sequence begins when data are written into the SPI\_DR register (Tx buffer).
  - The data are then parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission and then shifted out serially to the MOSI pin.
  - No data are received.
- In bidirectional mode, when receiving (BIDIMODE=1 and BIDIOE=0)
  - The sequence begins as soon as SPE=1 and BIDIOE=0.
  - The received data on the MOSI pin are shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
  - The transmitter is not activated and no data are shifted out serially to the MOSI pin.

### Start sequence in slave mode

- In full-duplex mode (BIDIMODE=0 and RXONLY=0)
  - The sequence begins when the slave device receives the clock signal and the first bit of the data on its MOSI pin. The 7 remaining bits are loaded into the shift register.
  - At the same time, the data are parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission, and then shifted out serially to the MISO

pin. The software must have written the data to be sent before the SPI master device initiates the transfer.

- In unidirectional receive-only mode (BIDIMODE=0 and RXONLY=1)
  - The sequence begins when the slave device receives the clock signal and the first bit of the data on its MOSI pin. The 7 remaining bits are loaded into the shift register.
  - The transmitter is not activated and no data are shifted out serially to the MISO pin.
- In bidirectional mode, when transmitting (BIDIMODE=1 and BIDIOE=1)
  - The sequence begins when the slave device receives the clock signal and the first bit in the Tx buffer is transmitted on the MISO pin.
  - The data are then parallel loaded from the Tx buffer into the 8-bit shift register during the first bit transmission and then shifted out serially to the MISO pin. The software must have written the data to be sent before the SPI master device initiates the transfer.
  - No data are received.
- In bidirectional mode, when receiving (BIDIMODE=1 and BIDIOE=0)
  - The sequence begins when the slave device receives the clock signal and the first bit of the data on its MISO pin.
  - The received data on the MISO pin are shifted in serially to the 8-bit shift register and then parallel loaded into the SPI\_DR register (Rx buffer).
  - The transmitter is not activated and no data are shifted out serially to the MISO pin.

### Handling data transmission and reception

The TXE flag (Tx buffer empty) is set when the data are transferred from the Tx buffer to the shift register. It indicates that the internal Tx buffer is ready to be loaded with the next data. An interrupt can be generated if the TXEIE bit in the SPI\_CR2 register is set. Clearing the TXE bit is performed by writing to the SPI\_DR register.

*Note: The software must ensure that the TXE flag is set to 1 before attempting to write to the Tx buffer. Otherwise, it overwrites the data previously written to the Tx buffer.*

The RXNE flag (Rx buffer not empty) is set on the last sampling clock edge, when the data are transferred from the shift register to the Rx buffer. It indicates that data are ready to be read from the SPI\_DR register. An interrupt can be generated if the RXNEIE bit in the SPI\_CR2 register is set. Clearing the RXNE bit is performed by reading the SPI\_DR register.

For some configurations, the BSY flag can be used during the last data transfer to wait until the completion of the transfer.

Full-duplex transmit and receive procedure in master or slave mode (BIDIMODE=0 and RXONLY=0)

The software has to follow this procedure to transmit and receive data (see [Figure 253](#) and [Figure 254](#)):

1. Enable the SPI by setting the SPE bit to 1.
2. Write the first data item to be transmitted into the SPI\_DR register (this clears the TXE flag).
3. Wait until TXE=1 and write the second data item to be transmitted. Then wait until RXNE=1 and read the SPI\_DR to get the first received data item (this clears the RXNE bit). Repeat this operation for each data item to be transmitted/received until the n-1 received data.
4. Wait until RXNE=1 and read the last received data.
5. Wait until TXE=1 and then wait until BSY=0 before disabling the SPI.

This procedure can also be implemented using dedicated interrupt subroutines launched at each rising edges of the RXNE or TXE flag.

**Figure 253. TXE/RXNE/BSY behavior in Master / full-duplex mode (BIDIMODE=0 and RXONLY=0) in case of continuous transfers**

**Figure 254. TXE/RXNE/BSY behavior in Slave / full-duplex mode (BIDIMODE=0, RXONLY=0) in case of continuous transfers**

### Transmit-only procedure (BIDIMODE=0 RXONLY=0)

In this mode, the procedure can be reduced as described below and the BSY bit can be used to wait until the completion of the transmission (see [Figure 255](#) and [Figure 256](#)).

1. Enable the SPI by setting the SPE bit to 1.
2. Write the first data item to send into the SPI\_DR register (this clears the TXE bit).
3. Wait until TXE=1 and write the next data item to be transmitted. Repeat this step for each data item to be transmitted.
4. After writing the last data item into the SPI\_DR register, wait until TXE=1, then wait until BSY=0, this indicates that the transmission of the last data is complete.

This procedure can be also implemented using dedicated interrupt subroutines launched at each rising edge of the TXE flag.

**Note:** During discontinuous communications, there is a 2 APB clock period delay between the write operation to SPI\_DR and the BSY bit setting. As a consequence, in transmit-only mode, it is mandatory to wait first until TXE is set and then until BSY is cleared after writing the last data.

After transmitting two data items in transmit-only mode, the OVR flag is set in the SPI\_SR register since the received data are never read.

**Figure 255. TXE/BSY behavior in Master transmit-only mode (BIDIMODE=0 and RXONLY=0) in case of continuous transfers**

**Figure 256. TXE/BSY in Slave transmit-only mode (BIDIMODE=0 and RXONLY=0) in case of continuous transfers**

### Bidirectional transmit procedure (BIDIMODE=1 and BIDIOE=1)

In this mode, the procedure is similar to the procedure in Transmit-only mode except that the BIDIMODE and BIDIOE bits both have to be set in the SPI\_CR2 register before enabling the SPI.

### Unidirectional receive-only procedure (BIDIMODE=0 and RXONLY=1)

In this mode, the procedure can be reduced as described below (see [Figure 257](#)):

1. Set the RXONLY bit in the SPI\_CR1 register.
2. Enable the SPI by setting the SPE bit to 1:
  - a) In master mode, this immediately activates the generation of the SCK clock, and data are serially received until the SPI is disabled (SPE=0).
  - b) In slave mode, data are received when the SPI master device drives NSS low and generates the SCK clock.
3. Wait until RXNE=1 and read the SPI\_DR register to get the received data (this clears the RXNE bit). Repeat this operation for each data item to be received.

This procedure can also be implemented using dedicated interrupt subroutines launched at each rising edge of the RXNE flag.

**Note:** *If it is required to disable the SPI after the last transfer, follow the recommendation described in [Section 28.3.8](#).*

**Figure 257. RXNE behavior in receive-only mode (BIDIRMODE=0 and RXONLY=1) in case of continuous transfers**

### Bidirectional receive procedure (BIDIMODE=1 and BIDIOE=0)

In this mode, the procedure is similar to the Receive-only mode procedure except that the BIDIMODE bit has to be set and the BIDIOE bit cleared in the SPI\_CR2 register before enabling the SPI.

### Continuous and discontinuous transfers

When transmitting data in master mode, if the software is fast enough to detect each rising edge of TXE (or TXE interrupt) and to immediately write to the SPI\_DR register before the ongoing data transfer is complete, the communication is said to be continuous. In this case, there is no discontinuity in the generation of the SPI clock between each data item and the BSY bit is never cleared between each data transfer.

On the contrary, if the software is not fast enough, this can lead to some discontinuities in the communication. In this case, the BSY bit is cleared between each data transmission (see [Figure 258](#)).

In Master receive-only mode (RXONLY=1), the communication is always continuous and the BSY flag is always read at 1.

In slave mode, the continuity of the communication is decided by the SPI master device. In any case, even if the communication is continuous, the BSY flag goes low between each transfer for a minimum duration of one SPI clock cycle (see [Figure 256](#)).

**Figure 258. TXE/BSY behavior when transmitting (BIDIRMODE=0 and RXONLY=0) in case of discontinuous transfers**

### 28.3.6 CRC calculation

A CRC calculator has been implemented for communication reliability. Separate CRC calculators are implemented for transmitted data and received data. The CRC is calculated using a programmable polynomial serially on each bit. It is calculated on the sampling clock edge defined by the CPHA and CPOL bits in the SPI\_CR1 register.

**Note:** *This SPI offers two kinds of CRC calculation standard which depend directly on the data frame format selected for the transmission and/or reception: 8-bit data (CR8) and 16-bit data (CRC16).*

CRC calculation is enabled by setting the CRCEN bit in the SPI\_CR1 register. This action resets the CRC registers (SPI\_RXCRCR and SPI\_TXCRCR). In full duplex or transmitter only mode, when the transfers are managed by the software (CPU mode), it is necessary to write the bit CRCNEXT immediately after the last data to be transferred is written to the SPI\_DR. At the end of this last data transfer, the SPI\_TXCRCR value is transmitted.

In receive only mode and when the transfers are managed by software (CPU mode), it is necessary to write the CRCNEXT bit after the second last data has been received. The CRC is received just after the last data reception and the CRC check is then performed.

At the end of data and CRC transfers, the CRCERR flag in the SPI\_SR register is set if corruption occurs during the transfer.

If data are present in the TX buffer, the CRC value is transmitted only after the transmission of the data byte. During CRC transmission, the CRC calculator is switched off and the register value remains unchanged.

SPI communication using the CRC is possible through the following procedure:

1. Program the CPOL, CPHA, LSBFirst, BR, SSM, SSI and MSTR values.
2. Program the polynomial in the SPI\_CRCPR register.
3. Enable the CRC calculation by setting the CRCEN bit in the SPI\_CR1 register. This also clears the SPI\_RXCRCR and SPI\_TXCRCR registers.
4. Enable the SPI by setting the SPE bit in the SPI\_CR1 register.
5. Start the communication and sustain the communication until all but one byte or half-word have been transmitted or received.
  - In full duplex or transmitter-only mode, when the transfers are managed by software, when writing the last byte or half word to the Tx buffer, set the CRCNEXT bit in the SPI\_CR1 register to indicate that the CRC is transmitted after the transmission of the last byte.
  - In receiver only mode, set the bit CRCNEXT just after the reception of the second to last data to prepare the SPI to enter in CRC Phase at the end of the reception of the last data. CRC calculation is frozen during the CRC transfer.
6. After the transfer of the last byte or half word, the SPI enters the CRC transfer and check phase. In full duplex mode or receiver-only mode, the received CRC is compared to the SPI\_RXCRCR value. If the value does not match, the CRCERR flag in SPI\_SR is set and an interrupt can be generated when the ERRIE bit in the SPI\_CR2 register is set.

**Note:** *When the SPI is in slave mode, be careful to enable CRC calculation only when the clock is stable, that is, when the clock is in the steady state. If not, a wrong CRC calculation may be done. In fact, the CRC is sensitive to the SCK slave input clock as soon as CRCEN is set, and this, whatever the value of the SPE bit.*

*With high bitrate frequencies, be careful when transmitting the CRC. As the number of used CPU cycles has to be as low as possible in the CRC transfer phase, it is forbidden to call software functions in the CRC transmission sequence to avoid errors in the last data and CRC reception. In fact, CRCNEXT bit has to be written before the end of the transmission/reception of the last data.*

*For high bit rate frequencies, it is advised to use the DMA mode to avoid the degradation of the SPI speed performance due to CPU accesses impacting the SPI bandwidth.*

*When the devices are configured as slaves and the NSS hardware mode is used, the NSS pin needs to be kept low between the data phase and the CRC phase.*

When the SPI is configured in slave mode with the CRC feature enabled, CRC calculation takes place even if a high level is applied on the NSS pin. This may happen for example in case of a multislave environment where the communication master addresses slaves alternately.

Between a slave deselection (high level on NSS) and a new slave selection (low level on NSS), the CRC value should be cleared on both master and slave sides in order to resynchronize the master and slave for their respective CRC calculation.

To clear the CRC, follow the procedure below:

1. Disable SPI (SPE = 0)
2. Clear the CRCEN bit
3. Set the CRCEN bit
4. Enable the SPI (SPE = 1)

### 28.3.7 Status flags

Four status flags are provided for the application to completely monitor the state of the SPI bus.

#### **Tx buffer empty flag (TXE)**

When it is set, this flag indicates that the Tx buffer is empty and the next data to be transmitted can be loaded into the buffer. The TXE flag is cleared when writing to the SPI\_DR register.

#### **Rx buffer not empty (RXNE)**

When set, this flag indicates that there are valid received data in the Rx buffer. It is cleared when SPI\_DR is read.

#### **BUSY flag**

This BSY flag is set and cleared by hardware (writing to this flag has no effect). The BSY flag indicates the state of the communication layer of the SPI.

When BSY is set, it indicates that the SPI is busy communicating. There is one exception in master mode / bidirectional receive mode (MSTR=1 and BDM=1 and BDOE=0) where the BSY flag is kept low during reception.

The BSY flag is useful to detect the end of a transfer if the software wants to disable the SPI and enter Halt mode (or disable the peripheral clock). This avoids corrupting the last transfer. For this, the procedure described below must be strictly respected.

The BSY flag is also useful to avoid write collisions in a multimaster system.

The BSY flag is set when a transfer starts, with the exception of master mode / bidirectional receive mode (MSTR=1 and BDM=1 and BDOE=0).

It is cleared:

- when a transfer is finished (except in master mode if the communication is continuous)
- when the SPI is disabled
- when a master mode fault occurs (MODF=1)

When communication is not continuous, the BSY flag is low between each communication.

When communication is continuous:

- in master mode, the BSY flag is kept high during all the transfers
- in slave mode, the BSY flag goes low for one SPI clock cycle between each transfer

*Note: Do not use the BSY flag to handle each data transmission or reception. It is better to use the TXE and RXNE flags instead.*

### 28.3.8 Disabling the SPI

When a transfer is terminated, the application can stop the communication by disabling the SPI peripheral. This is done by clearing the SPE bit.

For some configurations, disabling the SPI and entering the Halt mode while a transfer is ongoing can cause the current transfer to be corrupted and/or the BSY flag might become unreliable.

To avoid any of those effects, it is recommended to respect the following procedure when disabling the SPI:

#### **In master or slave full-duplex mode (BIDIMODE=0, RXONLY=0)**

1. Wait until RXNE=1 to receive the last data
2. Wait until TXE=1
3. Then wait until BSY=0
4. Disable the SPI (SPE=0) and, eventually, enter the Halt mode (or disable the peripheral clock)

#### **In master or slave unidirectional transmit-only mode (BIDIMODE=0, RXONLY=0) or bidirectional transmit mode (BIDIMODE=1, BIDIOE=1)**

After the last data is written into the SPI\_DR register:

1. Wait until TXE=1
2. Then wait until BSY=0
3. Disable the SPI (SPE=0) and, eventually, enter the Halt mode (or disable the peripheral clock)

#### **In master unidirectional receive-only mode (MSTR=1, BIDIMODE=0, RXONLY=1) or bidirectional receive mode (MSTR=1, BIDIMODE=1, BIDIOE=0)**

This case must be managed in a particular way to ensure that the SPI does not initiate a new transfer. The sequence below is valid only for SPI Motorola configuration (FRF bit set to 0):

1. Wait for the second to last occurrence of RXNE=1 (n-1)
2. Then wait for one SPI clock cycle (using a software loop) before disabling the SPI (SPE=0)
3. Then wait for the last RXNE=1 before entering the Halt mode (or disabling the peripheral clock)

When the SPI is configured in TI mode (Bit FRF set to 1), the following procedure has to be respected to avoid generating an undesired pulse on NSS when the SPI is disabled:

1. Wait for the second to last occurrence of RXNE = 1 (n-1).
2. Disable the SPI (SPE = 0) in the following window frame using a software loop:
  - After at least one SPI clock cycle,
  - Before the beginning of the LSB data transfer.

*Note:* In master bidirectional receive mode (MSTR=1 and BDM=1 and BDOE=0), the BSY flag is kept low during transfers.

**In slave receive-only mode (MSTR=0, BIDIMODE=0, RXONLY=1) or bidirectional receive mode (MSTR=0, BIDIMODE=1, BIDOE=0)**

1. You can disable the SPI (write SPE=1) at any time: the current transfer completes before the SPI is effectively disabled
2. Then, if you want to enter the Halt mode, you must first wait until BSY = 0 before entering the Halt mode (or disabling the peripheral clock).

**28.3.9 SPI communication using DMA (direct memory addressing)**

To operate at its maximum speed, the SPI needs to be fed with the data for transmission and the data received on the Rx buffer should be read to avoid overrun. To facilitate the transfers, the SPI features a DMA capability implementing a simple request/acknowledge protocol.

A DMA access is requested when the enable bit in the SPI\_CR2 register is enabled. Separate requests must be issued to the Tx and Rx buffers (see [Figure 259](#) and [Figure 260](#)):

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPI\_DR register (this clears the TXE flag).
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPI\_DR register (this clears the RXNE flag).

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received are not read.

When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (flag TCIF is set in the DMA\_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until TXE=1 and then until BSY=0.

*Note: During discontinuous communications, there is a 2 APB clock period delay between the write operation to SPI\_DR and the BSY bit setting. As a consequence, it is mandatory to wait first until TXE=1 and then until BSY=0 after writing the last data.*

Figure 259. Transmission using DMA

Figure 260. Reception using DMA

### DMA capability with CRC

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication are automatic that is without using the bit CRCNEXT. After the CRC reception, the CRC must be read in the SPI\_DR register to clear the RXNE flag.

At the end of data and CRC transfers, the CRCERR flag in SPI\_SR is set if corruption occurs during the transfer.

## 28.3.10 Error flags

### Master mode fault (MODF)

Master mode fault occurs when the master device has its NSS pin pulled low (in NSS hardware mode) or SSI bit low (in NSS software mode), this automatically sets the MODF bit. Master mode fault affects the SPI peripheral in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:

1. Make a read or write access to the SPI\_SR register while the MODF bit is set.
2. Then write to the SPI\_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence.

As a security, hardware does not allow the setting of the SPE and MSTR bits while the MODF bit is set.

In a slave device the MODF bit cannot be set. However, in a multimaster configuration, the device can be in slave mode with this MODF bit set. In this case, the MODF bit indicates that there might have been a multimaster conflict for system control. An interrupt routine can be used to recover cleanly from this state by performing a reset or returning to a default state.

### Overrun condition

An overrun condition occurs when the master device has sent data bytes and the slave device has not cleared the RXNE bit resulting from the previous data byte transmitted.

When an overrun condition occurs:

- the OVR bit is set and an interrupt is generated if the ERRIE bit is set.

In this case, the receiver buffer contents are not updated with the newly received data from the master device. A read from the SPI\_DR register returns this byte. All other subsequently transmitted bytes are lost.

Clearing the OVR bit is done by a read from the SPI\_DR register followed by a read access to the SPI\_SR register.

### CRC error

This flag is used to verify the validity of the value received when the CRCEN bit in the SPI\_CR1 register is set. The CRCERR flag in the SPI\_SR register is set if the value received in the shift register does not match the receiver SPI\_RXCRCR value.

### TI mode frame format error

A TI mode frame format error is detected when an NSS pulse occurs during an ongoing communication when the SPI is acting in slave mode and configured to conform to the TI mode protocol. When this error occurs, the FRE flag is set in the SPI\_SR register. The SPI is not disabled when an error occurs, the NSS pulse is ignored, and the SPI waits for the next NSS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the lost of two data bytes.

The FRE flag is cleared when SPI\_SR register is read. If the bit ERRIE is set, an interrupt is generated on the NSS error detection. In this case, the SPI should be disabled because data consistency is no more guaranteed and communications should be reinitiated by the master when the slave SPI is re-enabled.

**Figure 261. TI mode frame format error detection**

## 28.3.11 SPI interrupts

**Table 127. SPI interrupt requests**

| Interrupt event               | Event flag | Enable Control bit |
|-------------------------------|------------|--------------------|
| Transmit buffer empty flag    | TXE        | TXEIE              |
| Receive buffer not empty flag | RXNE       | RXNEIE             |
| Master mode fault event       | MODF       | ERRIE              |
| Overrun error                 | OVR        |                    |
| CRC error flag                | CRCERR     |                    |
| TI frame format error         | FRE        |                    |

## 28.4 I<sup>2</sup>S functional description

### 28.4.1 I<sup>2</sup>S general description

The block diagram of the I<sup>2</sup>S is shown in *Figure 262*.

**Figure 262. I<sup>2</sup>S block diagram**

1. I2S2ext SD and I2S3ext SD are the extended SD pins that control the I<sup>2</sup>S full duplex mode.

The SPI could function as an audio I<sup>2</sup>S interface when the I<sup>2</sup>S capability is enabled (by setting the I2SMOD bit in the SPI\_I2SCFGR register). This interface uses almost the same pins, flags and interrupts as the SPI.

The I<sup>2</sup>S shares three common pins with the SPI:

- SD: Serial Data (mapped on the MOSI pin) to transmit or receive the two time-multiplexed data channels (in half-duplex mode only).
- WS: Word Select (mapped on the NSS pin) is the data control signal output in master mode and input in slave mode.
- CK: Serial Clock (mapped on the SCK pin) is the serial clock output in master mode and serial clock input in slave mode.
- I2S2ext\_SD and I2S3ext\_SD: additional pins (mapped on the MISO pin) to control the I<sup>2</sup>S full duplex mode.

An additional pin could be used when a master clock output is needed for some external audio devices:

- MCK: Master Clock (mapped separately) is used, when the I<sup>2</sup>S is configured in master mode (and when the MCKOE bit in the SPI\_I2SPR register is set), to output this additional clock generated at a preconfigured frequency rate equal to  $256 \times F_S$ , where  $F_S$  is the audio sampling frequency.

The I<sup>2</sup>S uses its own clock generator to produce the communication clock when it is set in master mode. This clock generator is also the source of the master clock output. Two additional registers are available in I<sup>2</sup>S mode. One is linked to the clock generator configuration SPI\_I2SPR and the other one is a generic I<sup>2</sup>S configuration register SPI\_I2SCFGR (audio standard, slave/master mode, data format, packet frame, clock polarity, etc.).

The SPI\_CR1 register and all CRC registers are not used in the I<sup>2</sup>S mode. Likewise, the SSOE bit in the SPI\_CR2 register and the MODF and CRCERR bits in the SPI\_SR are not used.

The I<sup>2</sup>S uses the same SPI register for data transfer (SPI\_DR) in 16-bit wide mode.

### 28.4.2 I2S full duplex

To support I2S full duplex mode, two extra I<sup>2</sup>S instances called extended I2Ss (I2S2\_ext, I2S3\_ext) are available in addition to I2S2 and I2S3 (see [Figure 263](#)). The first I2S full-duplex interface is consequently based on I2S2 and I2S2\_ext, and the second one on I2S3 and I2S3\_ext.

*Note:* I2S2\_ext and I2S3\_ext are used only in full-duplex mode.

**Figure 263. I2S full duplex block diagram**

1. Where x can be 2 or 3.

I2Sx can operate in master mode. As a result:

- Only I2Sx can output SCK and WS in half duplex mode
- Only I2Sx can deliver SCK and WS to I2S2\_ext and I2S3\_ext in full duplex mode.

The extended I2Ss (I2Sx\_ext) can be used only in full duplex mode. The I2Sx\_ext operate always in slave mode.

Both I2Sx and I2Sx\_ext can be configured as transmitters or receivers.

### 28.4.3 Supported audio protocols

The four-line bus has to handle only audio data generally time-multiplexed on two channels: the right channel and the left channel. However there is only one 16-bit register for the transmission and the reception. So, it is up to the software to write into the data register the adequate value corresponding to the considered channel side, or to read the data from the data register and to identify the corresponding channel by checking the CHSIDE bit in the SPI\_SR register. Channel Left is always sent first followed by the channel right (CHSIDE has no meaning for the PCM protocol).

Four data and packet frames are available. Data may be sent with a format of:

- 16-bit data packed in 16-bit frame
- 16-bit data packed in 32-bit frame
- 24-bit data packed in 32-bit frame
- 32-bit data packed in 32-bit frame

When using 16-bit data extended on 32-bit packet, the first 16 bits (MSB) are the significant bits, the 16-bit LSB is forced to 0 without any need for software action or DMA request (only one read/write operation).

The 24-bit and 32-bit data frames need two CPU read or write operations to/from the SPI\_DR or two DMA operations if the DMA is preferred for the application. For 24-bit data frame specifically, the 8 nonsignificant bits are extended to 32 bits with 0-bits (by hardware).

For all data formats and communication standards, the most significant bit is always sent first (MSB first).

The I<sup>2</sup>S interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPI\_I2SCFGR register.

#### I<sup>2</sup>S Philips standard

For this standard, the WS signal is used to indicate which channel is being transmitted. It is activated one CK clock cycle before the first bit (MSB) is available.

**Figure 264. I<sup>2</sup>S Philips protocol waveforms (16/32-bit full accuracy, CPOL = 0)**

Data are latched on the falling edge of CK (for the transmitter) and are read on the rising edge (for the receiver). The WS signal is also latched on the falling edge of CK.

**Figure 265. I<sup>2</sup>S Philips standard waveforms (24-bit frame with CPOL = 0)**

This mode needs two write or read operations to/from the SPI\_DR.

- In transmission mode:  
if 0x8EAA33 has to be sent (24-bit):

**Figure 266. Transmitting 0x8EAA33**

- In reception mode:  
if data 0x8EAA33 is received:

**Figure 267. Receiving 0x8EAA33****Figure 268. I<sup>2</sup>S Philips standard (16-bit extended to 32-bit packet frame with CPOL = 0)**

When 16-bit data frame extended to 32-bit channel frame is selected during the I<sup>2</sup>S configuration phase, only one access to SPI\_DR is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

If the data to transmit or the received data are 0x76A3 (0x76A30000 extended to 32-bit), the operation shown in [Figure 269](#) is required.

**Figure 269. Example**

For transmission, each time an MSB is written to SPI\_DR, the TXE flag is set and its interrupt, if allowed, is generated to load SPI\_DR with the new value to send. This takes place even if 0x0000 have not yet been sent because it is done by hardware.

For reception, the RXNE flag is set and its interrupt, if allowed, is generated when the first 16 MSB half-word is received.

In this way, more time is provided between two write or read operations, which prevents underrun or overrun conditions (depending on the direction of the data transfer).

### MSB justified standard

For this standard, the WS signal is generated at the same time as the first data bit, which is the MSBit.

**Figure 270. MSB justified 16-bit or 32-bit full-accuracy length with CPOL = 0**

Data are latched on the falling edge of CK (for transmitter) and are read on the rising edge (for the receiver).

**Figure 271. MSB justified 24-bit frame length with CPOL = 0****Figure 272. MSB justified 16-bit extended to 32-bit packet frame with CPOL = 0**

### LSB justified standard

This standard is similar to the MSB justified standard (no difference for the 16-bit and 32-bit full-accuracy frame formats).

**Figure 273. LSB justified 16-bit or 32-bit full-accuracy with CPOL = 0****Figure 274. LSB justified 24-bit frame length with CPOL = 0**

- In transmission mode:  
If data 0x3478AE have to be transmitted, two write operations to the SPI\_DR register are required from software or by DMA. The operations are shown below.

**Figure 275. Operations required to transmit 0x3478AE**

- In reception mode:  
If data 0x3478AE are received, two successive read operations from SPI\_DR are required on each RXNE event.

**Figure 276. Operations required to receive 0x3478AE****Figure 277. LSB justified 16-bit extended to 32-bit packet frame with CPOL = 0**

When 16-bit data frame extended to 32-bit channel frame is selected during the I<sup>2</sup>S configuration phase, Only one access to SPI\_DR is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format. In this case it corresponds to the half-word MSB.

If the data to transmit or the received data are 0x76A3 (0x0000 76A3 extended to 32-bit), the operation shown in [Figure 278](#) is required.

**Figure 278. Example of LSB justified 16-bit extended to 32-bit packet frame**

In transmission mode, when TXE is asserted, the application has to write the data to be transmitted (in this case 0x76A3). The 0x000 field is transmitted first (extension on 32-bit). TXE is asserted again as soon as the effective data (0x76A3) is sent on SD.

In reception mode, RXNE is asserted as soon as the significant half-word is received (and not the 0x0000 field).

In this way, more time is provided between two write or read operations to prevent underrun or overrun conditions.

### PCM standard

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPI\_I2SCFGR.

**Figure 279. PCM standard waveforms (16-bit)**

For long frame synchronization, the WS signal assertion time is fixed 13 bits in master mode.

For short frame synchronization, the WS synchronization signal is only one cycle long.

**Figure 280. PCM standard waveforms (16-bit extended to 32-bit packet frame)**

**Note:** For both modes (master and slave) and for both synchronizations (short and long), the number of bits between two consecutive pieces of data (and so two synchronization signals) needs to be specified (DATLEN and CHLEN bits in the SPI\_I2SCFGR register) even in slave mode.

#### 28.4.4 Clock generator

The I<sup>2</sup>S bitrate determines the dataflow on the I<sup>2</sup>S data line and the I<sup>2</sup>S clock signal frequency.

I<sup>2</sup>S bitrate = number of bits per channel × number of channels × sampling audio frequency

For a 16-bit audio, left and right channel, the I<sup>2</sup>S bitrate is calculated as follows:

$$\text{I}^2\text{S bitrate} = 16 \times 2 \times F_S$$

It is I<sup>2</sup>S bitrate = 32 × 2 × F<sub>S</sub> if the packet length is 32-bit wide.

**Figure 281. Audio sampling frequency definition**

When the master mode is configured, a specific action needs to be taken to properly program the linear divider in order to communicate with the desired audio frequency.

**Figure 282. I<sup>2</sup>S clock generator architecture**

1. Where x could be 2 or 3.

**Figure 281** presents the communication clock architecture. To achieve high-quality audio performance, the I2SxCLK clock source can be either the PLLI2S output (through R division factor) or an external clock (mapped to I2S\_CKIN pin).

The audio sampling frequency can be 192 kHz, 96 kHz, or 48 kHz. In order to reach the desired frequency, the linear divider needs to be programmed according to the formulas below:

When the master clock is generated (MCKOE in the SPI\_I2SPR register is set):

$$F_S = I2SxCLK / [(16 \cdot 2) \cdot ((2 \cdot I2SDIV) + ODD) \cdot 8] \text{ when the channel frame is 16-bit wide}$$

$$F_S = I2SxCLK / [(32 \cdot 2) \cdot ((2 \cdot I2SDIV) + ODD) \cdot 4] \text{ when the channel frame is 32-bit wide}$$

When the master clock is disabled (MCKOE bit cleared):

$$F_S = I2SxCLK / [(16 \cdot 2) \cdot ((2 \cdot I2SDIV) + ODD)] \text{ when the channel frame is 16-bit wide}$$

$$F_S = I2SxCLK / [(32 \cdot 2) \cdot ((2 \cdot I2SDIV) + ODD)] \text{ when the channel frame is 32-bit wide}$$

**Table 128** provides example precision values for different clock configurations.

**Note:** Other configurations are possible that allow optimum clock precision.

Table 128. Audio frequency precision (for PLLM VCO = 1 MHz or 2 MHz)<sup>(1)</sup>

| Master clock | Target $f_s$ (Hz) | Data format | PLLI2SN | PLLI2SR | I2SDIV | I2SODD | Real $f_s$ (Hz) | Error   |
|--------------|-------------------|-------------|---------|---------|--------|--------|-----------------|---------|
| Disabled     | 8000              | 16-bit      | 192     | 2       | 187    | 1      | 8000            | 0.0000% |

1. This table gives only example values for different clock configurations. Other configurations allowing optimum clock precision are possible.

## 28.4.5 I<sup>2</sup>S master mode

The I<sup>2</sup>S can be configured as follows:

- In master mode for transmission or reception (half-duplex mode using I2Sx)
- In master mode transmission and reception (full duplex mode using I2Sx and I2Sx\_ext).

This means that the serial clock is generated on the CK pin as well as the Word Select signal WS. Master clock (MCK) may be output or not, thanks to the MCKOE bit in the SPI\_I2SPR register.

### Procedure

1. Select the I2SDIV[7:0] bits in the SPI\_I2SPR register to define the serial clock baud rate to reach the proper audio sample frequency. The ODD bit in the SPI\_I2SPR register also has to be defined.
2. Select the CKPOL bit to define the steady level for the communication clock. Set the MCKOE bit in the SPI\_I2SPR register if the master clock MCK needs to be provided to the external DAC/ADC audio component (the I2SDIV and ODD values should be computed depending on the state of the MCK output, for more details refer to [Section 28.4.4: Clock generator](#)).
3. Set the I2SMOD bit in SPI\_I2SCFGR to activate the I<sup>2</sup>S functionalities and choose the I<sup>2</sup>S standard through the I2SSTD[1:0] and PCMSYNC bits, the data length through the DATLEN[1:0] bits and the number of bits per channel by configuring the CHLEN bit. Select also the I<sup>2</sup>S master mode and direction (Transmitter or Receiver) through the I2SCFG[1:0] bits in the SPI\_I2SCFGR register.
4. If needed, select all the potential interruption sources and the DMA capabilities by writing the SPI\_CR2 register.
5. The I2SE bit in SPI\_I2SCFGR register must be set.

WS and CK are configured in output mode. MCK is also an output, if the MCKOE bit in SPI\_I2SPR is set.

### Transmission sequence

The transmission sequence begins when a half-word is written into the Tx buffer.

Assumedly, the first data written into the Tx buffer correspond to the channel Left data. When data are transferred from the Tx buffer to the shift register, TXE is set and data corresponding to the channel Right have to be written into the Tx buffer. The CHSIDE flag indicates which channel is to be transmitted. It has a meaning when the TXE flag is set because the CHSIDE flag is updated when TXE goes high.

A full frame has to be considered as a Left channel data transmission followed by a Right channel data transmission. It is not possible to have a partial frame where only the left channel is sent.

The data half-word is parallel loaded into the 16-bit shift register during the first bit transmission, and then shifted out, serially, to the MOSI/SD pin, MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPI\_CR2 register is set.

For more details about the write operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 28.4.3: Supported audio protocols](#).

To ensure a continuous audio data transmission, it is mandatory to write the SPI\_DR with the next data to transmit before the end of the current transmission.

To switch off the I<sup>2</sup>S, by clearing I2SE, it is mandatory to wait for TXE = 1 and BSY = 0.

### Reception sequence

The operating mode is the same as for the transmission mode except for the point 3 (refer to the procedure described in [Section 28.4.5: I<sup>2</sup>S master mode](#)), where the configuration should set the master reception mode through the I2SCFG[1:0] bits.

Whatever the data or channel length, the audio data are received by 16-bit packets. This means that each time the Rx buffer is full, the RXNE flag is set and an interrupt is generated

if the RXNEIE bit is set in SPI\_CR2 register. Depending on the data and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the Rx buffer.

Clearing the RXNE bit is performed by reading the SPI\_DR register.

CHSIDE is updated after each reception. It is sensitive to the WS signal generated by the I<sup>2</sup>S cell.

For more details about the read operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 28.4.3: Supported audio protocols](#).

If data are received while the previously received data have not been read yet, an overrun is generated and the OVR flag is set. If the ERRIE bit is set in the SPI\_CR2 register, an interrupt is generated to indicate the error.

To switch off the I<sup>2</sup>S, specific actions are required to ensure that the I<sup>2</sup>S completes the transfer cycle properly without initiating a new data transfer. The sequence depends on the configuration of the data and channel lengths, and on the audio protocol mode selected. In the case of:

- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) using the LSB justified mode (I2SSTD = 10)
  - a) Wait for the second to last RXNE = 1 (n – 1)
  - b) Then wait 17 I<sup>2</sup>S clock cycles (using a software loop)
  - c) Disable the I<sup>2</sup>S (I2SE = 0)
- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) in MSB justified, I<sup>2</sup>S or PCM modes (I2SSTD = 00, I2SSTD = 01 or I2SSTD = 11, respectively)
  - a) Wait for the last RXNE
  - b) Then wait 1 I<sup>2</sup>S clock cycle (using a software loop)
  - c) Disable the I<sup>2</sup>S (I2SE = 0)
- For all other combinations of DATLEN and CHLEN, whatever the audio mode selected through the I2SSTD bits, carry out the following sequence to switch off the I<sup>2</sup>S:
  - a) Wait for the second to last RXNE = 1 (n – 1)
  - b) Then wait one I<sup>2</sup>S clock cycle (using a software loop)
  - c) Disable the I<sup>2</sup>S (I2SE = 0)

*Note:* The BSY flag is kept low during transfers.

### 28.4.6 I<sup>2</sup>S slave mode

The I<sup>2</sup>S can be configured as follows:

- In slave mode for transmission or reception (half-duplex mode using I2Sx)
- In slave mode transmission and reception (full duplex mode using I2Sx and I2Sx\_ext).

The operating mode is following mainly the same rules as described for the I<sup>2</sup>S master configuration. In slave mode, there is no clock to be generated by the I<sup>2</sup>S interface. The clock and WS signals are input from the external master connected to the I<sup>2</sup>S interface. There is then no need, for the user, to configure the clock.

The configuration steps to follow are listed below:

1. Set the I2SMOD bit in the SPI\_I2SCFGR register to reach the I<sup>2</sup>S functionalities and choose the I<sup>2</sup>S standard through the I2SSTD[1:0] bits, the data length through the DATLEN[1:0] bits and the number of bits per channel for the frame configuring the CHLEN bit. Select also the mode (transmission or reception) for the slave through the I2SCFG[1:0] bits in SPI\_I2SCFGR register.
2. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPI\_CR2 register.
3. The I2SE bit in SPI\_I2SCFGR register must be set.

### Transmission sequence

The transmission sequence begins when the external master device sends the clock and when the NSS\_WS signal requests the transfer of data. The slave has to be enabled before the external master starts the communication. The I<sup>2</sup>S data register has to be loaded before the master initiates the communication.

For the I<sup>2</sup>S, MSB justified and LSB justified modes, the first data item to be written into the data register corresponds to the data for the left channel. When the communication starts, the data are transferred from the Tx buffer to the shift register. The TXE flag is then set in order to request the right channel data to be written into the I<sup>2</sup>S data register.

The CHSIDE flag indicates which channel is to be transmitted. Compared to the master transmission mode, in slave mode, CHSIDE is sensitive to the WS signal coming from the external master. This means that the slave needs to be ready to transmit the first data before the clock is generated by the master. WS assertion corresponds to left channel transmitted first.

*Note: The I2SE has to be written at least two PCLK cycles before the first clock of the master comes on the CK line.*

The data half-word is parallel-loaded into the 16-bit shift register (from the internal bus) during the first bit transmission, and then shifted out serially to the MOSI/SD pin MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPI\_CR2 register is set.

Note that the TXE flag should be checked to be at 1 before attempting to write the Tx buffer.

For more details about the write operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 28.4.3: Supported audio protocols](#).

To secure a continuous audio data transmission, it is mandatory to write the SPI\_DR register with the next data to transmit before the end of the current transmission. An underrun flag is set and an interrupt may be generated if the data are not written into the SPI\_DR register before the first clock edge of the next data communication. This indicates to the software that the transferred data are wrong. If the ERRIE bit is set into the SPI\_CR2 register, an interrupt is generated when the UDR flag in the SPI\_SR register goes high. In this case, it is mandatory to switch off the I<sup>2</sup>S and to restart a data transfer starting from the left channel.

To switch off the I<sup>2</sup>S, by clearing the I2SE bit, it is mandatory to wait for TXE = 1 and BSY = 0.

### Reception sequence

The operating mode is the same as for the transmission mode except for the point 1 (refer to the procedure described in [Section 28.4.6: I<sup>2</sup>S slave mode](#)), where the configuration should set the master reception mode using the I2SCFG[1:0] bits in the SPI\_I2SCFGR register.

Whatever the data length or the channel length, the audio data are received by 16-bit packets. This means that each time the RX buffer is full, the RXNE flag in the SPI\_SR register is set and an interrupt is generated if the RXNEIE bit is set in the SPI\_CR2 register. Depending on the data length and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the RX buffer.

The CHSIDE flag is updated each time data are received to be read from SPI\_DR. It is sensitive to the external WS line managed by the external master component.

Clearing the RXNE bit is performed by reading the SPI\_DR register.

For more details about the read operations depending on the I<sup>2</sup>S standard mode selected, refer to [Section 28.4.3: Supported audio protocols](#).

If data are received while the precedent received data have not yet been read, an overrun is generated and the OVR flag is set. If the bit ERRIE is set in the SPI\_CR2 register, an interrupt is generated to indicate the error.

To switch off the I<sup>2</sup>S in reception mode, I2SE has to be cleared immediately after receiving the last RXNE = 1.

*Note:* The external master components should have the capability of sending/receiving data in 16-bit or 32-bit packets via an audio channel.

### 28.4.7 Status flags

Three status flags are provided for the application to fully monitor the state of the I<sup>2</sup>S bus.

#### Busy flag (BSY)

The BSY flag is set and cleared by hardware (writing to this flag has no effect). It indicates the state of the communication layer of the I<sup>2</sup>S.

When BSY is set, it indicates that the I<sup>2</sup>S is busy communicating. There is one exception in master receive mode (I2SCFG = 11) where the BSY flag is kept low during reception.

The BSY flag is useful to detect the end of a transfer if the software needs to disable the I<sup>2</sup>S. This avoids corrupting the last transfer. For this, the procedure described below must be strictly respected.

The BSY flag is set when a transfer starts, except when the I<sup>2</sup>S is in master receiver mode.

The BSY flag is cleared:

- when a transfer completes (except in master transmit mode, in which the communication is supposed to be continuous)
- when the I<sup>2</sup>S is disabled

When communication is continuous:

- In master transmit mode, the BSY flag is kept high during all the transfers
- In slave mode, the BSY flag goes low for one I<sup>2</sup>S clock cycle between each transfer

*Note:* Do not use the BSY flag to handle each data transmission or reception. It is better to use the TXE and RXNE flags instead.

**Tx buffer empty flag (TXE)**

When set, this flag indicates that the Tx buffer is empty and the next data to be transmitted can then be loaded into it. The TXE flag is reset when the Tx buffer already contains data to be transmitted. It is also reset when the I<sup>2</sup>S is disabled (I2SE bit is reset).

**RX buffer not empty (RXNE)**

When set, this flag indicates that there are valid received data in the RX Buffer. It is reset when SPI\_DR register is read.

**Channel Side flag (CHSIDE)**

In transmission mode, this flag is refreshed when TXE goes high. It indicates the channel side to which the data to transfer on SD has to belong. In case of an underrun error event in slave transmission mode, this flag is not reliable and I<sup>2</sup>S needs to be switched off and switched on before resuming the communication.

In reception mode, this flag is refreshed when data are received into SPI\_DR. It indicates from which channel side data have been received. Note that in case of error (like OVR) this flag becomes meaningless and the I<sup>2</sup>S should be reset by disabling and then enabling it (with configuration if it needs changing).

This flag has no meaning in the PCM standard (for both Short and Long frame modes).

When the OVR or UDR flag in the SPI\_SR is set and the ERRIE bit in SPI\_CR2 is also set, an interrupt is generated. This interrupt can be cleared by reading the SPI\_SR status register (once the interrupt source has been cleared).

## 28.4.8 Error flags

There are three error flags for the I<sup>2</sup>S cell.

**Underrun flag (UDR)**

In slave transmission mode this flag is set when the first clock for data transmission appears while the software has not yet loaded any value into SPI\_DR. It is available when the I2SMOD bit in SPI\_I2SCFGR is set. An interrupt may be generated if the ERRIE bit in SPI\_CR2 is set.

The UDR bit is cleared by a read operation on the SPI\_SR register.

**Overrun flag (OVR)**

This flag is set when data are received and the previous data have not yet been read from SPI\_DR. As a result, the incoming data are lost. An interrupt may be generated if the ERRIE bit is set in SPI\_CR2.

In this case, the receive buffer contents are not updated with the newly received data from the transmitter device. A read operation to the SPI\_DR register returns the previous correctly received data. All other subsequently transmitted half-words are lost.

Clearing the OVR bit is done by a read operation on the SPI\_DR register followed by a read access to the SPI\_SR register.

**Frame error flag (FRE)**

This flag can be set by hardware only if the I2S is configured in Slave mode. It is set if the external master is changing the WS line at a moment when the slave is not expected this

change. If the synchronization is lost, to recover from this state and resynchronize the external master device with the I2S slave device, follow the steps below:

1. Disable the I2S
2. Re-enable it when the correct level is detected on the WS line (WS line is high in I2S mode, or low for MSB- or LSB-justified or PCM modes).

Desynchronization between the master and slave device may be due to noisy environment on the SCK communication clock or on the WS frame synchronization line. An error interrupt can be generated if the ERRIE bit is set. The desynchronization flag (FRE) is cleared by software when the status register is read.

### 28.4.9 I<sup>2</sup>S interrupts

[Table 129](#) provides the list of I<sup>2</sup>S interrupts.

**Table 129. I<sup>2</sup>S interrupt requests**

| Interrupt event               | Event flag | Enable Control bit |
|-------------------------------|------------|--------------------|
| Transmit buffer empty flag    | TXE        | TXEIE              |
| Receive buffer not empty flag | RXNE       | RXNEIE             |
| Overrun error                 | OVR        | ERRIE              |
| Underrun error                | UDR        |                    |
| Frame error flag              | FRE        | ERRIE              |

### 28.4.10 DMA features

DMA is working in exactly the same way as for the SPI mode. There is no difference on the I<sup>2</sup>S. Only the CRC feature is not available in I<sup>2</sup>S mode since there is no data transfer protection system.

## 28.5 SPI and I<sup>2</sup>S registers

The peripheral registers have to be accessed by half-words (16 bits) or words (32 bits).

### 28.5.1 SPI control register 1 (SPI\_CR1) (not used in I<sup>2</sup>S mode)

Address offset: 0x00

Reset value: 0x0000

| 15           | 14         | 13        | 12          | 11  | 10         | 9   | 8   | 7            | 6   | 5        | 4  | 3  | 2    | 1    | 0    |
|--------------|------------|-----------|-------------|-----|------------|-----|-----|--------------|-----|----------|----|----|------|------|------|
| BIDI<br>MODE | BIDI<br>OE | CRC<br>EN | CRC<br>NEXT | DFF | RX<br>ONLY | SSM | SSI | LSB<br>FIRST | SPE | BR [2:0] |    |    | MSTR | CPOL | CPHA |
| rw           | rw         | rw        | rw          | rw  | rw         | rw  | rw  | rw           | rw  | rw       | rw | rw | rw   | rw   | rw   |

**Bit 15 BIDIMODE:** Bidirectional data mode enable

0: 2-line unidirectional data mode selected

1: 1-line bidirectional data mode selected

*Note: This bit is not used in I<sup>2</sup>S mode*

**Bit 14 BIDIOE:** Output enable in bidirectional mode

This bit combined with the BIDImode bit selects the direction of transfer in bidirectional mode

0: Output disabled (receive-only mode)

1: Output enabled (transmit-only mode)

*Note: This bit is not used in I<sup>2</sup>S mode.*

*In master mode, the MOSI pin is used while the MISO pin is used in slave mode.*

**Bit 13 CRCEN:** Hardware CRC calculation enable

0: CRC calculation disabled

1: CRC calculation enabled

*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation.*

*It is not used in I<sup>2</sup>S mode.*

**Bit 12 CRCNEXT:** CRC transfer next

0: Data phase (no CRC phase)

1: Next transfer is CRC (CRC phase)

*Note: When the SPI is configured in full duplex or transmitter only modes, CRCNEXT must be written as soon as the last data is written to the SPI\_DR register.*

*When the SPI is configured in receiver only mode, CRCNEXT must be set after the second last data reception.*

*This bit should be kept cleared when the transfers are managed by DMA.*

*It is not used in I<sup>2</sup>S mode.*

**Bit 11 DFF:** Data frame format

0: 8-bit data frame format is selected for transmission/reception

1: 16-bit data frame format is selected for transmission/reception

*Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation.*

*It is not used in I<sup>2</sup>S mode.*

Bit 10 **RXONLY**: Receive only

This bit combined with the BIDImode bit selects the direction of transfer in 2-line unidirectional mode. This bit is also useful in a multislave system in which this particular slave is not accessed, the output from the accessed slave is not corrupted.

0: Full duplex (Transmit and receive)

1: Output disabled (Receive-only mode)

*Note: This bit is not used in I<sup>2</sup>S mode*

Bit 9 **SSM**: Software slave management

When the SSM bit is set, the NSS pin input is replaced with the value from the SSI bit.

0: Software slave management disabled

1: Software slave management enabled

*Note: This bit is not used in I<sup>2</sup>S mode and SPI TI mode*

Bit 8 **SSI**: Internal slave select

This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the NSS pin and the IO value of the NSS pin is ignored.

*Note: This bit is not used in I<sup>2</sup>S mode and SPI TI mode*

Bit 7 **LSBFIRST**: Frame format

0: MSB transmitted first

1: LSB transmitted first

*Note: This bit should not be changed when communication is ongoing.*

*It is not used in I<sup>2</sup>S mode and SPI TI mode*

Bit 6 **SPE**: SPI enable

0: Peripheral disabled

1: Peripheral enabled

*Note: This bit is not used in I<sup>2</sup>S mode.*

*When disabling the SPI, follow the procedure described in [Section 28.3.8](#).*

Bits 5:3 **BR[2:0]**: Baud rate control

000:  $f_{\text{PCLK}}/2$

001:  $f_{\text{PCLK}}/4$

010:  $f_{\text{PCLK}}/8$

011:  $f_{\text{PCLK}}/16$

100:  $f_{\text{PCLK}}/32$

101:  $f_{\text{PCLK}}/64$

110:  $f_{\text{PCLK}}/128$

111:  $f_{\text{PCLK}}/256$

*Note: These bits should not be changed when communication is ongoing.*

*They are not used in I<sup>2</sup>S mode.*

Bit 2 **MSTR**: Master selection

0: Slave configuration

1: Master configuration

*Note: This bit should not be changed when communication is ongoing.*

*It is not used in I<sup>2</sup>S mode.*

Bit1 **CPOL**: Clock polarity

0: CK to 0 when idle

1: CK to 1 when idle

*Note: This bit should not be changed when communication is ongoing.*

*It is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 0 **CPHA**: Clock phase

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

*Note: This bit should not be changed when communication is ongoing.*

*It is not used in I<sup>2</sup>S mode and SPI TI mode.*

## 28.5.2 SPI control register 2 (SPI\_CR2)

Address offset: 0x04

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6      | 5     | 4   | 3    | 2    | 1       | 0       |
|----------|----|----|----|----|----|---|---|-------|--------|-------|-----|------|------|---------|---------|
| Reserved |    |    |    |    |    |   |   | TXEIE | RXNEIE | ERRIE | FRF | Res. | SSOE | TXDMAEN | RXDMAEN |
|          |    |    |    |    |    |   |   | rw    | rw     | rw    | rw  |      | rw   | rw      | rw      |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TXEIE**: Tx buffer empty interrupt enable

0: TXE interrupt masked

1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.

Bit 6 **RXNEIE**: RX buffer not empty interrupt enable

0: RXNE interrupt masked

1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.

Bit 5 **ERRIE**: Error interrupt enable

This bit controls the generation of an interrupt when an error condition occurs )(CRCERR, OVR, MODF in SPI mode, FRE in TI mode and UDR, OVR, and FRE in I<sup>2</sup>S mode).

0: Error interrupt is masked

1: Error interrupt is enabled

Bit 4 **FRF**: Frame format

0: SPI Motorola mode

1 SPI TI mode

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bit 3 Reserved. Forced to 0 by hardware.

Bit 2 **SSOE**: SS output enable

0: SS output is disabled in master mode and the cell can work in multimaster configuration

1: SS output is enabled in master mode and when the cell is enabled. The cell cannot work in a multimaster environment.

*Note: This bit is not used in I<sup>2</sup>S mode and SPI TI mode.*

Bit 1 **TXDMAEN**: Tx buffer DMA enable

When this bit is set, the DMA request is made whenever the TXE flag is set.

0: Tx buffer DMA disabled

1: Tx buffer DMA enabled

Bit 0 **RxDMAEN**: Rx buffer DMA enable

When this bit is set, the DMA request is made whenever the RXNE flag is set.

0: Rx buffer DMA disabled

1: Rx buffer DMA enabled

### 28.5.3 SPI status register (SPI\_SR)

Address offset: 0x08

Reset value: 0x0002

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8   | 7   | 6   | 5    | 4          | 3   | 2      | 1   | 0    |
|----------|----|----|----|----|----|---|-----|-----|-----|------|------------|-----|--------|-----|------|
| Reserved |    |    |    |    |    |   | FRE | BSY | OVR | MODF | CRC<br>ERR | UDR | CHSIDE | TXE | RXNE |
|          |    |    |    |    |    |   | r   | r   | r   | r    | rc_w0      | r   | r      | r   | r    |

Bits 15:9 Reserved. Forced to 0 by hardware.

Bit 8 **FRE**: Frame format error

0: No frame format error

1: A frame format error occurred

This flag is set by hardware and cleared by software when the SPIx\_SR register is read.

*Note: This flag is used when the SPI operates in TI slave mode or I2S slave mode (refer to [Section 28.3.10](#)).*

Bit 7 **BSY**: Busy flag

0: SPI (or I2S) not busy

1: SPI (or I2S) is busy in communication or Tx buffer is not empty

This flag is set and cleared by hardware.

*Note: BSY flag must be used with caution: refer to [Section 28.3.7](#) and [Section 28.3.8](#).*

Bit 6 **OVR**: Overrun flag

0: No overrun occurred

1: Overrun occurred

This flag is set by hardware and reset by a software sequence (see [Section 28.3.10](#)).

Bit 5 **MODF**: Mode fault

0: No mode fault occurred

1: Mode fault occurred

This flag is set by hardware and reset by a software sequence (see [Section 28.3.10](#)).

*Note: This bit is not used in I<sup>2</sup>S mode*

Bit 4 **CRCERR**: CRC error flag

0: CRC value received matches the SPI\_RXCRCR value

1: CRC value received does not match the SPI\_RXCRCR value

This flag is set by hardware and cleared by software writing 0.

*Note: This bit is not used in I<sup>2</sup>S mode.*

Bit 3 **UDR**: Underrun flag

0: No underrun occurred

1: Underrun occurred

This flag is set by hardware and reset by a software sequence. Refer to [Section 28.4.8: Error flags](#) for the software sequence.

*Note: This bit is not used in SPI mode.*

Bit 2 **CHSIDE**: Channel side

0: Channel Left has to be transmitted or has been received

1: Channel Right has to be transmitted or has been received

*Note: This bit is not used for SPI mode and is meaningless in PCM mode.*

Bit 1 **TXE**: Transmit buffer empty

0: Tx buffer not empty

1: Tx buffer empty

Bit 0 **RXNE**: Receive buffer not empty

0: Rx buffer empty

1: Rx buffer not empty

## 28.5.4 SPI data register (SPI\_DR)

Address offset: 0x0C

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **DR[15:0]**: Data register

Data received or to be transmitted.

The data register is split into 2 buffers - one for writing (Transmit Buffer) and another one for reading (Receive buffer). A write to the data register writes into the Tx buffer and a read from the data register returns the value held in the Rx buffer.

*Note: These notes apply to SPI mode:*

*Depending on the data frame format selection bit (DFF in SPI\_CR1 register), the data sent or received is either 8-bit or 16-bit. This selection has to be made before enabling the SPI to ensure correct operation.*

*For an 8-bit data frame, the buffers are 8-bit and only the LSB of the register (SPI\_DR[7:0]) is used for transmission/reception. When in reception mode, the MSB of the register (SPI\_DR[15:8]) is forced to 0.*

*For a 16-bit data frame, the buffers are 16-bit and the entire register, SPI\_DR[15:0] is used for transmission/reception.*

### 28.5.5 SPI CRC polynomial register (SPI\_CRCPR) (not used in I<sup>2</sup>S mode)

Address offset: 0x10

Reset value: 0x0007

| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| CRCPOLY[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CRCPOLY[15:0]**: CRC polynomial register

This register contains the polynomial for the CRC calculation.

The CRC polynomial (0007h) is the reset value of this register. Another polynomial can be configured as required.

*Note: These bits are not used for the I<sup>2</sup>S mode.*

### 28.5.6 SPI RX CRC register (SPI\_RXCRCR) (not used in I<sup>2</sup>S mode)

Address offset: 0x14

Reset value: 0x0000

| 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| RXCRC[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r           | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **RXCRC[15:0]**: Rx CRC register

When CRC calculation is enabled, the RxCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPI\_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPI\_CRCPR register.

Only the 8 LSB bits are considered when the data frame format is set to be 8-bit data (DFF bit of SPI\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit data frame format is selected (DFF bit of the SPI\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY Flag is set could return an incorrect value. These bits are not used for I<sup>2</sup>S mode.*

### 28.5.7 SPI TX CRC register (SPI\_TXCRCR) (not used in I<sup>2</sup>S mode)

Address offset: 0x18

Reset value: 0x0000

|             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15          | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TXCRC[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r           | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **TXCRC[15:0]**: Tx CRC register

When CRC calculation is enabled, the TxCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPI\_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPI\_CRCPR register.

Only the 8 LSB bits are considered when the data frame format is set to be 8-bit data (DFF bit of SPI\_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit data frame format is selected (DFF bit of the SPI\_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY flag is set could return an incorrect value. These bits are not used for I<sup>2</sup>S mode.*

### 28.5.8 SPI\_I<sup>2</sup>S configuration register (SPI\_I2SCFGR)

Address offset: 0x1C

Reset value: 0x0000

|          |    |    |    |        |      |        |    |          |      |        |    |       |        |    |       |
|----------|----|----|----|--------|------|--------|----|----------|------|--------|----|-------|--------|----|-------|
| 15       | 14 | 13 | 12 | 11     | 10   | 9      | 8  | 7        | 6    | 5      | 4  | 3     | 2      | 1  | 0     |
| Reserved |    |    |    | I2SMOD | I2SE | I2SCFG |    | PCMSY NC | Res. | I2SSTD |    | CKPOL | DATLEN |    | CHLEN |
|          |    |    |    | rW     | rW   | rW     | rW | rW       |      | rW     | rW | rW    | rW     | rW | rW    |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **I2SMOD**: I2S mode selection

0: SPI mode is selected

1: I2S mode is selected

*Note: This bit should be configured when the SPI or I<sup>2</sup>S is disabled*

Bit 10 **I2SE**: I2S Enable

0: I<sup>2</sup>S peripheral is disabled

1: I<sup>2</sup>S peripheral is enabled

*Note: This bit is not used in SPI mode.*

Bits 9:8 **I2SCFG**: I2S configuration mode

00: Slave - transmit

01: Slave - receive

10: Master - transmit

11: Master - receive

*Note: This bit should be configured when the I<sup>2</sup>S is disabled.*

*It is not used in SPI mode.*

Bit 7 **PCMSYNC**: PCM frame synchronization

0: Short frame synchronization

1: Long frame synchronization

*Note: This bit has a meaning only if I2SSTD = 11 (PCM standard is used)*

*It is not used in SPI mode.*

Bit 6 Reserved: forced at 0 by hardware

Bits 5:4 **I2SSTD**: I2S standard selection

00: I<sup>2</sup>S Philips standard.

01: MSB justified standard (left justified)

10: LSB justified standard (right justified)

11: PCM standard

For more details on I<sup>2</sup>S standards, refer to [Section 28.4.3: Supported audio protocols](#). *Not used in SPI mode.*

*Note: For correct operation, these bits should be configured when the I<sup>2</sup>S is disabled.*

Bit 3 **CKPOL**: Steady state clock polarity

0: I<sup>2</sup>S clock steady state is low level

1: I<sup>2</sup>S clock steady state is high level

*Note: For correct operation, this bit should be configured when the I<sup>2</sup>S is disabled.*

*This bit is not used in SPI mode*

Bits 2:1 **DATLEN**: Data length to be transferred

00: 16-bit data length

01: 24-bit data length

10: 32-bit data length

11: Not allowed

*Note: For correct operation, these bits should be configured when the I<sup>2</sup>S is disabled.*

*This bit is not used in SPI mode.*

Bit 0 **CHLEN**: Channel length (number of bits per audio channel)

0: 16-bit wide

1: 32-bit wide

The bit write operation has a meaning only if DATLEN = 00 otherwise the channel length is fixed to 32-bit by hardware whatever the value filled in. *Not used in SPI mode.*

*Note: For correct operation, this bit should be configured when the I<sup>2</sup>S is disabled.*

### 28.5.9 SPI\_I<sup>2</sup>S prescaler register (SPI\_I2SPR)

Address offset: 0x20

Reset value: 0000 0010 (0x0002)

| 15       | 14 | 13 | 12 | 11 | 10 | 9     | 8   | 7      | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|-------|-----|--------|---|---|---|---|---|---|---|
| Reserved |    |    |    |    |    | MCKOE | ODD | I2SDIV |   |   |   |   |   |   |   |
|          |    |    |    |    |    | rw    | rw  | rw     |   |   |   |   |   |   |   |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **MCKOE**: Master clock output enable

0: Master clock output is disabled

1: Master clock output is enabled

*Note: This bit should be configured when the I<sup>2</sup>S is disabled. It is used only when the I<sup>2</sup>S is in master mode.*

*This bit is not used in SPI mode.*

Bit 8 **ODD**: Odd factor for the prescaler

0: real divider value is = I2SDIV \*2

1: real divider value is = (I2SDIV \* 2)+1

Refer to [Section 28.4.4: Clock generator](#). Not used in SPI mode.

*Note: This bit should be configured when the I<sup>2</sup>S is disabled. It is used only when the I<sup>2</sup>S is in master mode.*

Bits 7:0 **I2SDIV**: I2S Linear prescaler

I2SDIV [7:0] = 0 or I2SDIV [7:0] = 1 are forbidden values.

Refer to [Section 28.4.4: Clock generator](#). Not used in SPI mode.

*Note: These bits should be configured when the I<sup>2</sup>S is disabled. It is used only when the I<sup>2</sup>S is in master mode.*

## 28.5.10 SPI register map

The table provides shows the SPI register map and reset values.

**Table 130. SPI register map and reset values**

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15            | 14     | 13    | 12      | 11     | 10     | 9      | 8       | 7        | 6      | 5        | 4      | 3     | 2        | 1    | 0       |         |      |   |   |   |
|--------|-------------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---------------|--------|-------|---------|--------|--------|--------|---------|----------|--------|----------|--------|-------|----------|------|---------|---------|------|---|---|---|

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 29 Serial audio interface (SAI)

This section applies to the STM32F42xxx and STM32F43xxx family.

### 29.1 Introduction

The SAI interface (serial audio interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, free protocol, and AC'97 protocols may be addressed for example.

To bring this level of flexibility and configurability, the SAI contains two audio sub-blocks that are fully independent of each other. Each audio sub-block is connected to up to 4 pins (SD, SCK, FS, MCLK). Some of these pins can be shared if the two sub-blocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

The SAI can work in master or slave configuration. The audio sub-blocks can be either receiver or transmitter and can work synchronously or not (with respect to the other one).

## 29.2 Main features

- Two independent audio sub-blocks which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio sub-block.
- Synchronous or asynchronous mode between the audio sub-blocks.
- Master or slave configuration independent for both audio sub-blocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio sub-blocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Peripheral with large configurability and flexibility allowing to target as example the following audio protocol: I2S, LSB or MSB-justified, PCM/DSP, free protocol mode, AC'97
- Up to 16 slots available with configurable size and with the possibility to select which ones are active in the audio frame.
- Number of bits by frame may be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC'97 mode in reception.
- Interruption sources when enabled:
  - Errors,
  - FIFO requests.
- DMA interface with 2 dedicated channels to handle access to the dedicated integrated FIFO of each SAI audio sub-block.

## 29.3 Functional block diagram

The block diagram of the SAI is shown in [Figure 283](#).

**Figure 283. Functional block diagram**

The SAI is mainly composed of two audio sub-blocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA in order to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages each dedicated pins for a given audio block in the SAI. If the two blocks are synchronized, this controller reduces the number of I/Os used, freeing up an FS pin, an SCK pin and eventually an MCLK pin, making them general purpose I/Os

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set-up the desired protocols (audio frame waveform generator).

The audio block can be a transmitter or receiver, in master or slave mode. The master mode means the bit clock SCK and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave

mode definition. In AC'97 protocol, it is an SAI output even if the SAI (link controller) is set-up to consume the SCK clock (and so to be in Slave mode).

## 29.4 Main SAI modes

Each audio sub-block of the SAI can be configured to be master or slave via bit MODE[0] in the SAI\_xCR1 register of the selected audio block.

In master mode:

- The bit clock is generated by the SAI using the clock generator on pin SCK\_A or SCK\_B (depending which audio block is declared as a master in the SAI).
- The dedicated pin SCK\_x is considered as an output.

In slave mode:

- The slave must be enabled before the master is enabled.
- The slave audio block's SCK clock I/O pin is considered input if it is configured in asynchronous mode.
- If the audio block is declared synchronous with the second audio block in the SAI, its SCK I/O pin is released to leave it free to be used as a general purpose I/O and is connected internally to the SCK pin of the device with which it is synchronized.

Each audio sub-block can be independently defined as a transmitter or receiver by bit MODE[1] in the SAI\_xCR1 register of the relevant audio block. The I/O pin SD is defined respectively as an output or an input.

It is possible to declare two master audio blocks in the same SAI with two different MCLK and SCK clock frequencies (they have to be declared asynchronous).

Each of the audio blocks in the SAI are enabled by bit SAIxEN in the SAI\_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock line, data line and synchronization line in slave mode.

In master TX mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave TX mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:

1. Write into the SAI\_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 000b (FIFO empty).
3. Enable the audio block in slave transmitter mode.

## 29.5 SAI synchronization mode

### Internal synchronization

An audio block can be declared synchronous with the second audio block. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block declared as synchronous with the other one sees its own SCK\_x, FS\_x, and MCLK\_x pins released to bring them back as GPIOs. The one declared asynchronous is the one for which the I/O pins FS\_x and SCK\_x and MCLK\_x (if the audio block is considered as master) are considered.

Typically, the audio block synchronous mode may be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as master and the other as slave, or both can be slaves; with one block declared as asynchronous (respective bit SYNCEN[1:0] = 00 in SAI\_xCR1) and the other one declared as synchronous with the other audio block (respective bit SYNCEN[1:0] = 01 in the SAI\_xCR1).

*Note:* APB frequency PCLK must be greater or equal to twice the bit rate clock frequency (due to internal resynchronization stages).

## 29.6 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI\_xCR1 register. The data sizes may be 8-, 10-, 16-, 20-, 24- or 32-bit. During the transfer, either the MSB or the LSB of the data are sent first, depending on the configuration of bit LSBFIRST in the SAI\_xCR1 register.

## 29.7 Frame synchronization

The FS signal acts as the Frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable in order to target the different audio protocols with their own specificities concerning this Frame synchronization behavior. This configurability is done using register SAI\_xFRCR. [Figure 284](#) gives a view of this flexibility.

**Figure 284. Audio frame**

In AC'97 mode (bit PRTCFG[1:0] = 10 in the SAI\_xCR1 register), the frame synchronization shape is forced to be configured to target these protocols. The SAI\_xFRCR register value is ignored.

Each audio block is independent and so each requires a specific configuration.

### 29.7.1 Frame length

- Master mode: The audio frame length can be configured up to 256 bit clock, setting bit FRL[7:0] in the SAI\_xFRCR register. If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit are extended to 0 or the SD line is released to HI-z depending the state of bit TRIS in the SAI\_xCR2 register (refer to [Section 29.12.4](#)). In reception mode, the remaining bit is ignored.
- Slave mode: The audio frame length is mainly used in order to specify to the slave the number of bit clocks per audio frame sent by the external master. It is used mainly to detect from the master, any anticipated or late occurrence of the Frame synchronization signal during an on-going audio frame. An error is generated in such case. For more details please refer to the [Section 29.13](#).

The number of bits in the frame is equal to  $FRL[7:0] + 1$ .

The minimum number of bits to transfer in an audio frame is 8. This is the case when the data size is 8-bit and only one slot is defined in NBSLOT[3:0] in the SAI\_xSLOTR register (NBSLOT[3:0] = 0000 for slot 0).

In master mode:

- If bit NODIV in the SAI\_xCR1 register is cleared, the frame length should be aligned to a number equal to a power of 2, from 8 to 256. This is to ensure that an audio frame contains an integer number of MCLK pulses per bit clock, which ensures correct operation of the external DAC/ADC inside the decoders. If the value set in FRL[7:0] does not respect this rule, flag WCKCFG is set when the audio block is enabled and an interrupt is generated if bit WCKCFGIE is set in the SAI\_xIM register. The SAI is automatically disabled.
- If bit NODIV in the SAI\_xCR1 register is set, the FRL[7:0] bit can take any of the values without constraint since the input clock of the audio block should be equal to the bit clock. There is no MCLK\_x clock which can be output. MCLK\_x output pad is automatically disabled.

In slave mode, there are no constraints for the FRL[7:0] bit configuration in the SAI\_xFRCR register.

### 29.7.2 Frame synchronization polarity

Bit FSPOL in the SAI\_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start to transmit or to receive. Start of frame is synchronized to this signal. It is effective only if the start of frame is not detected during an on-going communication and assimilated to an anticipated start of frame (refer to [Section 29.13](#)).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIxEN bit in the SAI\_xCR1 register is cleared. If no data is present in the FIFO at the end of the previous audio frame, an underrun condition is managed as described in [Section 29.13](#), but there is no interruption in the audio communication flow.

### 29.7.3 Frame synchronization active level length

Bit FSALL[6:0] in the SAI\_xFRCR register configures the length of the active level of the Frame synchronization signal. The length can be set from 1 to 128 bit clock SCK.

The active length may be half of the frame length in I2S, LSB or MSB-justified modes for instance, or one-bit wide for PCM/DSP or free protocol mode, or even 16-bit length in AC'97.

### 29.7.4 Frame synchronization offset

Depending on the audio protocol targeted in the application, the Frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (as for instance, respectively, in I2S standard protocol and in MSB-justified protocol). Bit FSOFF in the SAI\_xFRCR register makes the choice.

### 29.7.5 FS signal role

The FS signal may have a different meaning depending on the FS function. Bit FSDEF in the SAI\_xFRCR register selects which meaning it has. It may be either:

- 0: a start of frame, like for instance the PCM/DSP, free protocol, AC'97, audio protocols,
- 1: a start of frame and a channel side identification within the audio frame like for the I2S, the MSB or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half of the number for the left channel and half of the number for the right channel. If the number of bit clock on half audio frame is greater than the number of slots dedicated to a channel side, if TRIS = 0, 0 is sent for transmission for the remaining bit clock in the SAI\_xCR2 register, otherwise if TRIS = 1, the SD line is released to HI-Z. In reception, the remaining bit clock are not considered until the channel side changes.

**Figure 285. FS role is start of frame + channel side identification (FSDEF = TRIS = 1)**

1. The frame length should be even.

If bit FSDEF in SAI\_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in bit NBSLOT[3:0] in SAI\_xSLOTR multiplied by the number of bits by slot configured in bit SLOTSZ[1:0] in SAI\_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI\_xFRCR register), then,

- if TRIS = 0 in the SAI\_xCR2 register, the remaining bit after the last slot is forced to 0 until the end of frame in case of transmission,
- if TRIS = 1, the line is released to HI-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.

**Figure 286. FS role is start of frame (FSDEF = 0)**

## 29.8 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to the configured setting of bit NBSLOT[3:0] in the SAI\_xSLOTR register +1. The maximum number of slots per audio frame is fixed at 16.

For AC'97 protocol (when bit PRTCFG[1:0] = 10), the number of slots is automatically set to target the protocol specification, and the value of NBSLOT[3:0] is ignored.

Each slot can be defined as a valid slot, or not, by setting bit SLOTEN[15:0] in the SAI\_xSLOTR register. In an audio frame, during the transfer of a non-valid slot, 0 value is forced on the data line or the SD data line is released to HI-z (refer to [Section 29.12.4](#)) if the audio block is transmitter, or the received value from the end of this slot is ignored. Consequently, there is no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in the [Figure 287](#). The size of the slots is selected by setting bit SLOTSZ[1:0] in the SAI\_xSLOTR register. The size is applied identically for each slot in an audio frame.

**Figure 287. Slot size configuration with FBOFF = 0 in SAI\_xSLOTR**

It is possible to choose the position of the first data bit to transfer within the slots, this offset is configured by bit FBOFF[5:0] in the SAI\_xSLOTR register. 0 values are injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

**Figure 288. First bit offset**

It is mandatory to respect the following conditions in order to avoid bad SAI behavior:

$$\text{FBOFF} \leq (\text{SLOTSZ} - \text{DS}),$$

$$\text{DS} \leq \text{SLOTSZ},$$

$$\text{NBSLOT} \times \text{SLOTSZ} \leq \text{FRL (frame length)},$$

The number of slots should be even when bit FSDEF in the SAI\_xFRCR register is set.

In AC'97 (bit PRTCFG[1:0] = 10), the slot size is automatically set as defined in [Section 29.11](#).

## 29.9 SAI clock generator

Each audio block has its own clock generator to make these two blocks completely independent. There is no difference in terms of functionality between these two clock generators. They are exactly the same.

When the audio block is defined as Master, the clock generator generates the communication clock (the bit clock) and the master clock for external decoders.

When the audio block is defined as slave, the clock generator is OFF.

[Figure 289](#) illustrates the architecture of the audio block clock generator.

**Figure 289. Audio block clock generator overview**

**Note:** If NoDiv is set to 1, the MCLK\_x signal is set at 0 level if this pin is configured as the SAI pin in GPIO peripherals.

The clock source for the clock generator comes from the product clock controller. The SAI\_CK\_x clock is equivalent to the master clock which may be divided for the external decoders using bit MCKDIV[3:0]:

$MCLK\_x = SAI\_CK\_x / (MCKDIV[3:0] * 2)$ , if MCKDIV[3:0] is not equal to 0000.

$MCLK\_x = SAI\_CK\_x$ , if MCKDIV[3:0] is equal to 0000.

MCLK\_x signal is used only in free protocol mode.

The division must be even in order to keep 50% on the Duty cycle on the MCLK output and on the SCK\_x clock. If bit MCKDIV[3:0] = 0000, division by one is applied to have  $MCLK\_x = SAI\_CK\_x$ .

In the SAI, the single ratio  $MCLK/FS = 256$  is considered. Mostly, three frequency ranges are encountered as illustrated in the [Table 131](#).

Table 131. Example of possible audio frequency sampling range

| Input SAI_CK_x clock frequency | Most usual audio frequency sampling achievable | MCKDIV[3:0]        |
|--------------------------------|------------------------------------------------|--------------------|
| 192 kHz x 256                  | 192 kHz                                        | MCKDIV[3:0] = 0000 |
|                                | 96 kHz                                         | MCKDIV[3:0] = 0001 |
|                                | 48 kHz                                         | MCKDIV[3:0] = 0010 |
|                                | 16 kHz                                         | MCKDIV[3:0] = 0100 |
|                                | 8 kHz                                          | MCKDIV[3:0] = 1000 |
| 44.1 kHz x 256                 | 44.1 kHz                                       | MCKDIV[3:0] = 0000 |
|                                | 22.05 kHz                                      | MCKDIV[3:0] = 0001 |
|                                | 11.025 kHz                                     | MCKDIV[3:0] = 0010 |
| SAI_CK_x = MCLK <sup>(1)</sup> | MCLK                                           | MCKDIV[3:0] = 0000 |

1. This may happen when the product clock controller selects an external clock source, instead of PLL clock.

The master clock may be generated externally on an I/O pad for external decoders if the corresponding audio block is declared as master with bit NODIV = 0 in the SAI\_xCR1 register. In slave, the value set in this last bit is ignored since the clock generator is OFF, and the MCLK\_x I/O pin is released for use as a general purpose I/O.

The bit clock is derived from the master clock. The bit clock divider sets the divider factor between the bit clock SCK\_x and the master clock MCLK\_x following the formula:

$$SCK\_x = MCLK \times (FRL[7:0] + 1) / 256$$

where:

256 is the fixed ratio between MCLK and the audio frequency sampling.

FRL[7:0] is the number of bit clock - 1 in the audio frame, configured in the SAI\_xFRCR register.

It is mandatory in master mode that (FRL[7:0] + 1) should be equal to a number with a power of 2 (refer to [Section 29.7](#)) in order to have an even integer number of MCLK\_x pulses by bit clock. The 50% duty cycle is guaranteed on the bit clock SCK\_x.

The SAI\_CK\_x clock can be also equal to the bit clock frequency. In this case, bit NODIV in the SAI\_xCR1 register should be set and the value inside the MCKDIV divider and the bit clock divider is ignored. In this case, the number of bits per frame is fully configurable without the need to be equal to a power of two.

The bit clock strobing edge on SCK can be configured by bit CKSTR in the SAI\_xCR1 register.

## 29.10 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending if the block is defined to be a transmitter or a receiver, the FIFO is written or read, respectively. There is therefore only one FIFO request linked to FREQ bit in the SAI\_xSR register.

An interrupt is generated if FREQIE bit is enabled in the SAI\_xIM register. This depends on:

- FIFO threshold setting (FLTH bits in SAI\_CR2)
- Communication direction transmitter or receiver (see [Section : Interrupt generation in transmitter mode](#) and [Section : Interrupt generation in reception mode](#))

### Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:

- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO empty (FTH[2:0] set to 000b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI\_XSR register) if no data are available in SAI\_xDR register (FLTH[2:0] bits in SAI\_xSR is less than 001b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when the FIFO became not empty (FLTH[2:0] bits in SAI\_xSR are different from 000b) i.e one or more data are stored in the FIFO.
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO quarter full (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI\_XSR register) if less than a quarter of the FIFO contains data (FLTH[2:0] bits in SAI\_xSR are less than 010b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when at least a quarter of the FIFO contains data (FLTH[2:0] bits in SAI\_xSR are higher or equal to 010b).
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO half full (FTH[2:0] set to 010b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI\_XSR register) if less than half of the FIFO contains data (FLTH[2:0] bits in SAI\_xSR are less than 011b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when at least half of the FIFO contains data (FLTH[2:0] bits in SAI\_xSR are higher or equal to 011b).
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO three quarter (FTH[2:0] set to 011b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if less than three quarters of the FIFO contain data (FLTH[2:0] bits in SAI\_xSR are less than 100b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when at least three quarters of the FIFO contain data (FLTH[2:0] bits in SAI\_xSR are higher or equal to 100b).
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO full (FTH[2:0] set to 100b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if the FIFO is not full (FLTH[2:0] bits in SAI\_xSR is less than 101b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when the FIFO is full (FLTH[2:0] bits in SAI\_xSR is equal to 101b value).

### Interrupt generation in reception mode

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO empty (FTH[2:0] set to 000b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if at least one data is available in SAI\_xDR register (FLTH[2:0] bits in SAI\_xSR is higher or equal to 001b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when the FIFO became empty (FLTH[2:0] bits in SAI\_xSR is equal to 000b) i.e no data is stored in FIFO.
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO quarter fully (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if at less one quarter of the FIFO data locations are available

(FLTH[2:0] bits in SAI\_xSR is higher or equal to 010b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLTH[2:0] bits in SAI\_xSR is less than 010b).

- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO half fully (FTH[2:0] set to 010b value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if at least half of the FIFO data locations are available (FLTH[2:0] bits in SAI\_xSR is higher or equal to 011b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLTH[2:0] bits in SAI\_xSR is less than 011b).
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if at least three quarters of the FIFO data locations are available (FLTH[2:0] bits in SAI\_xSR is higher or equal to 100b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLTH[2:0] bits in SAI\_xSR is less than 100b).
- When the FIFO threshold bits in SAI\_XCR2 register are configured as FIFO full (FTH[2:0] set to 100b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI\_XSR register) if the FIFO is full (FLTH[2:0] bits in SAI\_xSR is equal to 101b). This Interrupt (FREQ bit in SAI\_XSR register) is cleared by hardware when the FIFO is not full (FLTH[2:0] bits in SAI\_xSR is less than 101b).

Like interrupt generation, the SAI can use the DMA if DMAEN bit in the SAI\_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interruption generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO allocation whatever the access size. Each FIFO word contains one audio frame. FIFO pointers are incremented by one word after each access to the SAI\_xDR register.

Data should be right aligned when it is written in the SAI\_xDR.

Data received are right aligned in the SAI\_xDR.

The FIFO pointers can be reinitialized when the SAI is disabled by setting bit FFLUSH in the SAI\_xCR2 register. If FFLUSH is set when the SAI is enabled, the data present in the FIFO are lost automatically.

## 29.11 AC'97 link controller

The SAI is able to work as an AC'97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set bit PRTCFG[1:0] in the SAI\_xCR1 register to 10. When AC'97 mode is selected the data sizes that can be used are 16-bit or 20-bit only, else SAI behavior is not guaranteed.

- Bits NBSLOT[3:0] and SLOTSZ[1:0] are consequently ignored.
- The number of slots is fixed at 13 slots. The first one is 16 bits wide and all the others are 20 bits wide (data slots).
- Bit FBOFF[5:0] in the SAI\_xSLOTR register is ignored
- The SAI\_xFRCR register is ignored.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC'97 controller link drives the FS signal whatever the master or slave configuration.

Figure 290 presents an AC'97 audio frame structure.

**Figure 290. AC'97 audio frame**

**Note:** In AC'97 protocol, bit 2 of the tag is reserved (always 0), so whatever the value written in the SAI FIFO, bit 2 of the TAG is forced to 0 level.

For more details about TAG representation, please refer to the AC'97 protocol standard.

One SAI can be used to target an AC'97 point-to-point communication.

In receiver mode, the SAI acting as an AC'97 link controller does not require any FIFO request and so no data storage in the FIFO when the codec ready bit in the slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI\_xIM register, flag CNRDY is set in the SAI\_xSR register and an interrupt is generated. This flag is dedicated to the AC'97 protocol.

## 29.12 Specific features

The SAI has some specific functions which can be useful depending on the audio protocol selected. These functions are accessible through specific bits in the SAI\_xCR2 register.

### 29.12.1 Mute mode

Mute mode may be used when the audio block is a transmitter or receiver.

#### Transmitter

In transmitter mode, Mute mode can be selected at anytime. Mute mode is active for entire audio frames. The bit MUTE in the SAI\_xCR2 register requests Mute mode when it is set during an on-going frame.

The mute mode bit is strobed only at the end of the frame. If set at this time, the mute mode is active at the beginning of the new audio frame, for a complete frame, until the next end of frame, it then strobes the bit to determine if the next frame is still a mute frame.

If the number of slots set in bit NBSLOT[3:0] in the SAI\_xSLOTR register is lower than or equal to two, it is possible to specify if the value sent during the Mute mode is 0 or if it is the last value of each slot. The selection is done via bit MUTEVAL in the SAI\_xCR2 register.

If the number of slots set in bit NBSLOT[3:0] in the SAI\_xSLOTR register is greater than two, MUTEVAL bit in the SAI\_xCR2 has no meaning as 0 values are sent on each bit on each slot.

During Mute mode, the FIFO pointers are still incremented, meaning that data which was present in the FIFO and for which the Mute mode is requested is discarded.

#### Receiver

In receiver mode, it is possible to detect a Mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (bit MUTECONT[5:0] in the SAI\_xCR2 register).

When the number of MUTE frames is detected, flag MUTEDET in the SAI\_xSR register is set and an interrupt can be generated if bit MUTEDETIE is set in the SAI\_xCR2.

The mute frame counter is cleared when the audio block is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the specified value in bit MUTECONT[5:0]. Then the interrupt event is re-armed when the counter is cleared.

### 29.12.2 MONO/STEREO function

In transmission mode, it is possible to address the Mono mode without any data pre-processing in memory when the number of slot is equal to 2 (NBSLOT[3:0] = 0001 in the SAI\_xSLOTR). In such a case, the access to and from the FIFO is reduced by two since in transmission, the data for slot 0 is duplicated into data slot 1.

To select the Mono feature, set bit MONO in the SAI\_xCR1 register.

In reception mode, bit MONO can be set and has a meaning only if the number of slots is equal to 2 like for the transmission mode. When it is set, only the data of slot 0 are stored in the FIFO. The data belonging to slot 1 are discarded since in this case, it is supposed to be the same as the previous slot. If the data flux in reception is a real stereo audio flow with a

distinct and different left and right data, bit MONO has no meaning. The conversion from the output stereo file to the equivalent mono file is done by software.

**Note:** To enable Mono mode, NBSLOT and SLOTEN must equal two and MONO bit set to 1.

### 29.12.3 Companding mode

Telecommunication applications may require to process the data to transmit or to receive with a data companding algorithm.

Depending on the COMP[1:0] bit in the SAI\_xCR2 register (used only when free protocol mode is selected), the software may choose to process or not the data before sending it on SD serial output line (compression) or to expand the data after the reception on SD serial input line (expansion) as illustrated in Figure 291. The two companding modes supported are the  $\mu$ -Law and the A-Law log which are a part of the CCITT G.711 recommendation.

The companding standard employed in the United States and Japan is the  $\mu$ -Law and allows 14 bits of dynamic range (COMP[1:0] = 10 in the SAI\_xCR2 register).

The European companding standard is A-Law and allows 13 bits of dynamic range (COMP[1:0] = 11 in the SAI\_xCR2 register).

Companding standard ( $\mu$ -Law or A-Law) can be computed based on 1's complement or 2's complement representation depending on the CPL bit setting in the SAI\_xCR2 register.

The  $\mu$ -Law and A-Law formats encode data into 8-bit code elements with MSB alignment. Companded data is always 8 bits wide. For this reason, bit DS[2:0] in the SAI\_xCR1 register is forced to 010 when the SAI audio block is enabled (bit SAIxEN = 1 in the SAI\_xCR1 register) and when the COMP[1:0] bit selects one of these two companding modes.

If no companding processing is required, COMP[1:0] bit in the SAI\_xCR2 register should be kept cleared.

**Figure 291. Data companding hardware in an audio block in the SAI**

**Note:** Not applicable when AC'97 selected.

Expansion or compression mode is automatically selected by the SAI configuration.

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI\_xCR2 register, the compression mode is applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm is applied.

#### 29.12.4 Output data line management on an inactive slot

In transmitter mode, it is possible to choose the behavior of the SD line in output when an inactive slot is sent on the data line (via bit TRIS in the SAI\_xCR2 register when the SAI is disabled).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in HI-z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters do not attempt to drive the same SD output pin simultaneously, which could result in a short circuit. In order to ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting bit SLOTSZ[1:0] = 10 in the SAI\_xSLOTR register. Then, the SD output pin is tristated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line is tristated when the padding to 0 is done to complete the audio frame.

*Figure 292* illustrates these behaviors.

Figure 292. Tristate strategy on SD output line on an inactive slot

When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI\_xFRCR register), the tristate mode is managed according to [Figure 293](#) (where bit TRIS in the SAI\_xCR1 register = 1, and FSDEF=1, and half frame length > number of slots/2, and NBSLOT=6).

Figure 293. Tristate on output data line in a protocol like I2S

If the TRIS bit in the SAI\_xCR2 register is cleared, all the High impedance states on the SD output line on [Figure 292](#) and [Figure 293](#) are replaced by a drive with a value of 0.

## 29.13 Error flags

The SAI embeds some error flags:

- FIFO overrun/underrun,
- Anticipated frame synchronization detection,
- Late frame synchronization detection,
- Codec not ready (AC'97 exclusively),
- Wrong clock configuration in master mode.

### 29.13.1 FIFO overrun/underrun (OVRUDR)

The FIFO Overrun/Underrun bit is called OVRUDR in the SAI\_xSR register.

The overrun or underrun errors occupy the same bit since an audio block can be either receiver or transmitter and each audio block in an SAI has its own SAI\_xSR register.

#### Overrun

When the audio block is configured as receiver, an overrun condition may appear if data is received in an audio frame when the FIFO is full and is not able to store the received data. In this case, the received data is lost, the flag OVRUDR in the SAI\_xSR register is set and an interrupt is generated if bit OVRUDRIE is set in the SAI\_xIM register. The slot number from which the overrun occurs, is stored internally. No more data are stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver stores new data (from new audio frame) from the slot number which

was stored internally when the overrun condition was detected, and this, to avoid data slot de-alignment in the destination memory (refer to [Figure 294](#)).

The OVRUDR flag is cleared when bit COVRUDR is set in the SAI\_xCLRFR register.

**Figure 294. Overrun detection error**

## Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data needs to be transmitted (the audio block configuration (Master or Slave) is not relevant). If an underrun is detected, the software must resynchronize data and slot. Proceed as follows:

1. Disable the SAI peripheral by resetting the SAIEN bit of the SAI\_xCR1 register. Check that the SAI has been disabled by reading back the SAIEN bit (SAIEN should be equal to 0).
2. Flush the Tx FIFO through the FFLUS bit of the SAI\_xCR2 register.
3. Re-assigned to the correct data to be transferred on the first active slot of the new frame.
4. Re-enabling the SAI peripheral (SAIEN bit set to 1).

The underrun event sets the OVRUDR flag in the SAI\_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI\_xIM register. To clear this flag, set the COVRUDR bit in the SAI\_xCLRFR register.

Figure 295. FIFO underrun event

MS192347V2

### 29.13.2 Anticipated frame synchronisation detection (AFSDET)

This flag AFSDET is used only in Slave mode. In master mode, it is never asserted. It informs about the detection of a frame synchronisation (FS) earlier than expected since the frame length, the frame polarity, the frame offset are defined and known.

Early detection sets flag AFSDET in the SAI\_xSR register.

This detection has no effect on the current audio frame which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

If bit AFSDETIE is set in the SAI\_xIM register, an interrupt is generated. To clear the flag AFSDET, bit CAFSDET in the SAI\_xCLRFR register has to be set.

To resynchronize with the master after Anticipated frame detection error, four steps should be respected:

1. SAI block should be disabled by resetting SAIEN bit in SAI\_xCR1 register, to be sure that the SAI is disabled SAIEN bit is should be equal to 0 (reading back this bit).
2. FIFO should be flushed via FFLUS bit in SAI\_xCR2 register.
3. Re-enabling the SAI peripheral (SAIEN bit set to 1) then the SAI.
4. SAI block waits for the assertion on FS to restart the synchronization with master.

**Note:** *This flag is not asserted in AC'97 since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave.*

### 29.13.3 Late frame synchronization detection

Flag LFSDET in the SAI\_xSR register can be set only when the SAI audio block is defined as slave. The frame length, the frame polarity and the frame offset configuration are known in register SAI\_xFRCR.

If the external master does not send the FS signal at the expecting time (generating the signal too late), the flag LFSDET in the SAI\_xSR register is set and an interrupt is generated if bit LFSDETIE in the SAI\_xIM register is set.

The flag is cleared when bit CLFSDET is set in the SAI\_xCLRFR register.

The late frame synchronisation detection flag is set when the error is detected, SAI needs to be resynchronized with the master (the four steps described above should be respected).

This detection and flag assertion can detect glitches on the SCK clock in a noisy environment, detected by the state machine of the audio block. It could incorrectly shift the SAI audio block state machine from one state in the current audio frame, thus corrupting the frame.

There is no corruption if the external master is not managing the audio data frame transfer in a continuous mode, which should not be the case for most application purposes. In this case, flag LFSDET is set.

*Note: This flag is not asserted in AC'97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave.*

#### 29.13.4 Codec not ready (CNRDY AC'97)

The flag CNRDY in the SAI\_xSR register is relevant only if the SAI audio block is configured to work in AC'97 mode (bit PRTCFG[1:0] = 10 in the SAI\_xCR1 register). If bit CNRDYIE is set in the SAI\_xIM register, an interrupt is generated when the flag CNRDY is set.

It is asserted when the codec is not ready to communicate during the reception of the TAG 0 (slot0) of the AC'97 audio frame. In this case, no data are automatically stored into the FIFO since the codec is not ready, until the TAG 0 indicates that the codec is ready. All the active slots defined in the SAI\_xSLOTR register are captured when the codec is ready.

To clear the flag, bit CCNRDY in the SAI\_xCLRFR register has to be set.

#### 29.13.5 Wrong clock configuration in master mode (with NODIV = 0)

When the audio block is master (MODE[1] = 0 in the SAI\_xCR1 register) and if bit NODIV in the SAI\_xCR1 is clear, the flag WCKCFG is set if bit FRL[7:0] in the SAI\_xFRCR is not set with a proper value when the SAIxEN bit in the SAI\_xCR1 register is set, in order to respect this following rule:

$$(FRL[7,0]) + 1 = 2^n$$

where n is in the range from 3 to 8.

If bit WCKCFGIE is set, an interrupt is generated when flag WCKCFG is set in the SAI\_xSR register. To clear the flag, set bit CWCKCFG bit in the SAI\_xCLRFR register.

When bit WCKCFG is set, the audio block is automatically disabled, clearing bit SAIxEN in the SAI\_xCR1 register via hardware.

The above formula is intended to guarantee that the number of MCLK pulses by bit clock is an even integer in the audio frame with a 50% duty cycle bit clock generation to guarantee the good quality of the audio sounds or acquisitions.

## 29.14 Interrupt sources

The SAI has 7 possible interrupt sources as illustrated by [Table 132](#).

**Table 132. Interrupt sources**

| Interrupt source | Interrupt group | Audio block mode                               | Interrupt enable               | Interrupt clear                                                                                                                                                               |
|------------------|-----------------|------------------------------------------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FREQ             | FREQ            | Master or Slave Receiver or transmitter        | FREQIE in SAI_xIM register     | Depend on:<br>- FIFO threshold setting (FLTH bits in SAI_CR2)<br>- Communication direction transmitter or receiver<br>for more details please refer to Internal FIFOs section |
| OVRUDR           | ERROR           | Master or Slave Receiver or transmitter        | OVRUDRIE in SAI_xIM register   | COVRUDR = 1 in SAI_xCLRFR register                                                                                                                                            |
| AFSDET           | ERROR           | Slave (Not used in AC'97 mode)                 | AFSDETIIE in SAI_xIM register  | CAFSDET = 1 in SAI_xCLRFR register                                                                                                                                            |
| LFSDET           | ERROR           | Slave (Not used in AC'97 mode)                 | LFSDETIIE in SAI_xIM register  | CLFSDET = 1 in SAI_xCLRFR register                                                                                                                                            |
| CNRDY            | ERROR           | Slave (Only in AC'97 mode)                     | CNRDYIE in SAI_xIM register    | CCNRDY = 1 in SAI_xCLRFR register                                                                                                                                             |
| MUTEDET          | MUTE            | Master or slave Receiver mode only             | MUTEDETIIE in SAI_xIM register | CMUTEDET = 1 in SAI_xCLRFR register                                                                                                                                           |
| WCKCFG           | ERROR           | Master with NODIV = 0 in the SAI_xCR1 register | WCKCFGIE in SAI_xIM register   | CWCKCFG = 1 in SAI_xCLRFR register                                                                                                                                            |

Below are the SAI configuration steps to follow when an interrupt occurs:

1. Disable SAI interrupt.
2. Configure SAI.
3. Configure SAI interrupt source.
4. Enable SAI.

## 29.15 Disabling the SAI

The audio block in the SAI can be disabled at any moment by clearing bit SAIxEN in the SAI\_xCR1 register. All the frames that have already started are automatically completed before the total extinction of the SAI. Bit SAIxEN in the SAI\_xCR1 register stays high until the SAI is completely switched-off at the end of the current audio frame transfer.

If there is an audio block in the SAI synchronous with the other one, the one which is the master must be disabled first.

## 29.16 SAI DMA interface

In order to free the CPU and to optimize the bus bandwidth, each SAI audio block has an independent DMA interface in order to read or to write into the SAI\_xDR register (to hit the internal FIFO). There is one DMA channel per audio block following basic DMA request/acknowledge protocol.

To configure the audio block to transfer through the DMA interface, set bit DMAEN in the SAI\_xCR1 register. The DMA request is managed directly by the FIFO controller depend of FIFO threshold level (for more details please refer to Internal FIFOs section). DMA direction is linked to the SAI audio block configuration:

- If the audio block is a transmitter, the audio block's FIFO controller outputs a DMA request to load the FIFO with data written in the SAI\_xDR register.
- If the audio block is a receiver, the DMA request concerns read operations from the SAI\_xDR register.

Below are the SAI configuration steps followed when DMA is used:

1. Configure SAI and FIFO Threshold level (in order to specify when the DMA request to be launched)
2. Configure SAI DMA channel
3. Enable DMA
4. Enable SAI

*Note:* Before configuring the SAI block, the SAI DMA channel must be disabled.

## 29.17 SAI registers

### 29.17.1 SAI x configuration register 1 (SAI\_xCR1) where x is A or B

Address offset: Block A: 0x004

Address offset: Block B: 0x024

Reset value: 0x0000 0040

|          |    |             |      |             |    |       |              |             |    |    |      |              |      |           |        |
|----------|----|-------------|------|-------------|----|-------|--------------|-------------|----|----|------|--------------|------|-----------|--------|
| 31       | 30 | 29          | 28   | 27          | 26 | 25    | 24           | 23          | 22 | 21 | 20   | 19           | 18   | 17        | 16     |
| Reserved |    |             |      |             |    |       |              | MCKDIV[3:0] |    |    |      | NODIV        | Res. | DMAEN     | SAIxEN |
|          |    |             |      |             |    |       |              | rw          | rw | rw | rw   | rw           |      | rw        | rw     |
| 15       | 14 | 13          | 12   | 11          | 10 | 9     | 8            | 7           | 6  | 5  | 4    | 3            | 2    | 1         | 0      |
| Reserved |    | OutDri<br>v | MONO | SYNCEN[1:0] |    | CKSTR | LSBFIR<br>ST | DS[2:0]     |    |    | Res. | PRTCFCG[1:0] |      | MODE[1:0] |        |
|          |    | rw          | rw   | rw          | rw | rw    | rw           | rw          | rw | rw |      | rw           | rw   | rw        | rw     |

Bits 31:24 Reserved, always read as 0.

Bit 23:20 **MCKDIV[3:0]**: *Master clock divider*. These bits are set and cleared by software.

0000: Divides by 1 the master clock input.

Otherwise, The Master clock frequency is calculated accordingly to the following formula:

$$MCLK_x = SAI\_CK\_x / (MCKDIV[3:0] * 2)$$

These bits have no meaning when the audio block is slave.

They have to be configured when the audio block is disabled.

Bit 19 **NODIV**: No divider. This bit is set and cleared by software.

0: Master Clock divider is enabled

1: No divider used in the clock generator (in this case Master Clock Divider bit has no effect)

Bit 18 Reserved, always read as 0.

Bit 17 **DMAEN**: DMA enable. This bit is set and cleared by software.

0: DMA is disabled

1: DMA is enabled

*Note: In receiver mode, the bits MODE must be configured before setting bit DMAEN to avoid a DMA request since the audio block is transmitter after reset (default setting)*

Bit 16 **SAIxEN**: Audio block enable where x is A or B. This bit is set by software. It is cleared by hardware, after disabling it by software (writing the bit low), the audio is completely disabled (waiting for the end of the current frame).

0: Audio block is disabled

1: Audio block is enabled: this bit can be set only if it is at 0 during the write operation (means the SAI is completely disabled before being re-enabled).

This bit allows to control the state of the audio block. If it is disabled somewhere in an audio frame, the ongoing transfer is complete and the cell is totally disabled at the end of this audio frame transfer.

*Note: When SAIx block is configured as master mode, clock must be present on the input of the SAI before setting SAIxEN bit.*

Bits 15:14 Reserved, always read as 0.

Bit 13 **OUTDRIV**: Output drive. This bit is set and cleared by software.

0: Audio block output driven when SAIEN is set

1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block but after the audio block configuration.*

Bit 12 **MONO**: Mono mode. This bit is set and cleared by software.

0: Stereo mode

1: Mono mode.

This bit has a meaning only when the number of slots is equal to 2.

When the Mono mode is selected, the data of the slot 0 data is duplicated on the slot 1 when the audio block is a transmitter. In reception mode, the slot1 is discarded and only the data received from the slot 0 are stored.

Refer to [Section 29.12.2](#) for more details.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable. This bit is set and cleared by software.

00: audio block is asynchronous.

01: audio block is synchronous with the other internal audio block. In this case audio block should be configured in Slave mode

10: Reserved.

11: Not used

These bits have to be configured when the audio block is disabled.

Bit 9 **CKSTR**: Clock strobing edge. This bit is set and cleared by software.

0: data strobing edge is falling edge of SCK

1: data strobing edge is rising edge of SCK

This bit has to be configured when the audio block is disabled.

Bit 8 **LSBFIRST**: Least significant bit first. This bit is set and cleared by software.

0: data is transferred with the MSB of the data first

1: data is transferred with the LSB of the data first

This bit has to be configured when the audio block is disabled.

This bit has no meaning in AC'97 audio protocol since in AC'97 data is transferred with the MSB of the data first.

Bits 7:5 **DS[2:0]**: Data size. These bits are set and cleared by software.

000: Not used

001: Not used

010: 8-bit

011: 10-bit

100: 16-bit

101: 20-bit

110: 24-bit

111: 32-bit

When the companding mode is selected (bit COMP[1:0]), these DS[1:0] are ignored since the data size is fixed to 8-bit mode by the algorithm itself.

These bits must be configured when the audio block is disabled.

*Note: When AC'97 mode is selected the data sizes that can be used are: 16-bit or 20-bit only, else SAI behavior is not guaranteed.*

Bit 4 Reserved, always read as 0.

Bits 3:2 **PRTCFG[1:0]**: Protocol configuration. These bits are set and cleared by software.

- 00: Free protocol
- 01: Not used
- 10: AC'97 protocol
- 11: Not used

Free protocol selection allows to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, free protocol, PCM/DSP) setting most of the configuration register bits as well as frame configuration register.

These bits have to be configured when the audio block is disabled.

Bits 1:0 **MODE[1:0]**: Audio block mode. These bits are set and cleared by software.

- 00: Master transmitter
- 01: Master receiver
- 10: Slave transmitter
- 11: Slave receiver

These bits have to be configured when the audio block is disabled.

*Note: In Master transmitter mode the audio block starts to generate the FS and clocks*

**29.17.2 SAI x configuration register 2 (SAI\_xCR2) where x is A or B**

Address offset: Block A: 0x008

Address offset: Block B: 0x028

Reset value: 0x0000 0000

|           |    |     |              |    |    |    |    |    |          |      |      |       |     |    |    |
|-----------|----|-----|--------------|----|----|----|----|----|----------|------|------|-------|-----|----|----|
| 31        | 30 | 29  | 28           | 27 | 26 | 25 | 24 | 23 | 22       | 21   | 20   | 19    | 18  | 17 | 16 |
| Reserved  |    |     |              |    |    |    |    |    |          |      |      |       |     |    |    |
| 15        | 14 | 13  | 12           | 11 | 10 | 9  | 8  | 7  | 6        | 5    | 4    | 3     | 2   | 1  | 0  |
| COMP[1:0] |    | CPL | MUTECNT[5:0] |    |    |    |    |    | MUTE VAL | Mute | TRIS | FFLUS | FTH |    |    |
| rw        | rw | rw  | rw           | rw | rw | rw | rw | rw | rw       | rw   | rw   | rw    | rw  | rw | rw |

Bits 31:16 Reserved, always read as 0

Bits 15:14 **COMP[1:0]**: Companding mode. These bits are set and cleared by software.

00: No companding algorithm

01: Reserved.

10:  $\mu$ -Law algorithm

11: A-Law algorithm

The  $\mu$ -Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on *ComPLEMENT bit*.

The data expansion or data compression are determined by the state of bit MODE[0].

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to [Section 29.12.3](#) for more details.

*Note:* Companding mode is applicable only when free protocol mode is selected.

Bit 13 **CPL**: Complement bit. This bit is set and cleared by software.

It defines the type of complement to be used for companding mode

0: 1's complement representation.

1: 2's complement representation.

*Note:* This bit has effect only when the companding mode is  $\mu$ -Law algorithm or A-Law algorithm.

Bits 12:7 **MUTECNT[5:0]**: Mute counter. These bits are set and cleared by software.

These bits are used only in reception mode.

The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.

Refer to [Section 29.12.1](#) for more details.

Bit 6 **MUTEVAL**: Mute value. This bit is set and cleared by software. This bit has to be written before enabling the audio block: SAIxEN.

0: Bit value 0 is sent during the MUTE mode.

1: Last values are sent during the MUTE mode.

This bit has a meaning only when the audio block is a transmitter and when the number of slots is lower or equal to 2 and if the MUTE bit is set.

If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of this MUTEVAL bit.

If the number of slot is lower or equal to 2 and MUTEVAL = 1, the mute value transmitted for each slot is the one sent during the previous frame.

Refer to [Section 29.12.1](#) for more details.

Bit 5 **MUTE**: Mute. This bit is set and cleared by software.

0: No Mute mode.

1: Mute mode enabled.

This bit has a meaning only when the audio block is a transmitter. The MUTE value is linked to the MUTEVAL value if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.

Refer to [Section 29.12.1](#) for more details.

Bit 4 **TRIS**: Tristate management on data line. This bit is set and cleared by software.

0: SD output line is still driven by the SAI when a slot is inactive.

1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

This bit has a meaning only if the audio block is configured to be a transmitter.

This bit should be configured when SAI is disabled.

Refer to [Section 29.12.4](#) for more details.

Bit 3 **FFLUSH**: FIFO flush. This bit is set by software. It is always read low.

0: No FIFO flush.

1: FIFO flush.

Writing 1 to the bit triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared.

Data still present in the FIFO are lost in such case (no more transmission or received data lost).

This bit should be configured when SAI is disabled.

Before flushing SAI, DMA stream/interruption must be disabled

Bits 2:0 **FTH**: FIFO threshold. This bit is set and cleared by software.

000: FIFO empty

001: ¼ FIFO

010: ½ FIFO

011: ¾ FIFO

100: FIFO full

101: Reserved

110: Reserved

111: Reserved

**29.17.3 SAI x frame configuration register (SAI\_XFRCR) where x is A or B**

Address offset: Block A: 0x00C

Address offset: Block B: 0x02C

Reset value: 0x0000 0007

*Note: This register has no meaning in AC'97 audio protocol*

| 31       | 30         | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18    | 17    | 16    |

|          |            |    |    |    |    |    |    |          |    |    |    |    | rw    | rw    | r     |
| 15       | 14         | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2     | 1     | 0     |
| Res.     | FSALL[6:0] |    |    |    |    |    |    | FRL[7:0] |    |    |    |    |       |       |       |
|          | rw         | rw | rw | rw | rw | rw | rw | rw       | rw | rw | rw | rw | rw    | rw    | rw    |

Bits 31:19 Reserved, always read as 0.

Bit 18 **FSOFF**: Frame synchronization offset. This bit is set and cleared by software.

0: FS is asserted on the first bit of the slot 0.

1: FS is asserted one bit before the first bit of the slot 0.

This bit has no meaning and is not used in AC'97 audio block configuration.

This bit must be configured when the audio block is disabled.

Bit 17 **FSPOL**: Frame synchronization polarity. This bit is set and cleared by software

0: FS is active low (falling edge)

1: FS is active high (rising edge)

This bit is used to configure the level of the start of frame on the FS signal.

This bit has no meaning and is not used in AC'97 audio block configuration.

This bit must be configured when the audio block is disabled.

Bit 16 **FSDEF**: Frame synchronization definition. This bit is set and cleared by software.

0: FS signal is a start frame signal

1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI\_ASLOTR register has to be even. It means that there is half of this number of slots dedicated for the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...)

This bit has no meaning and is not used in AC'97 audio block configuration.

This bit must be configured when the audio block is disabled.

Bit 15 Reserved, always read as 0.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length. These bits are set and cleared by software  
The value set in these bits specifies the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame  
These bits have no meaning and are not used in AC'97 audio block configuration.  
These bits must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length. These bits are set and cleared by software.  
They define the length of the audio frame. More precisely, these bits define the number of SCK clocks for each audio frame.  
The number of bits in the frame is equal to FRL[7:0] + 1.  
The minimum number of bits to transfer in an audio frame has to be equal to 8 or else the audio block has unexpected behavior. This is the case when the data size is 8-bit and only one slot 0 is defined in NBSLOT[4:0] in the SAI\_ASLOTR register (NBSLOT[3:0] = 0000).  
In master mode, if the master clock MCLK\_x pin is declared as an output, the frame length should be aligned to a number equal to a power of 2, from 8 to 256 in order to keep in an audio frame, an integer number of MCLK pulses by bit clock for correct operation for external DAC/ADC inside the decoders.  
The Frame length should be even.  
These bits have no meaning and are not used in AC'97 audio block configuration.  
*Note: The FRL[7:0] bitfield must be configured when the audio block is disabled.*

**29.17.4 SAI x slot register (SAI\_xSLOTR) where x is A or B**

Address offset: Block A: 0x010

Address offset: Block B: 0x030

Reset value: 0x0000 0000

*Note: This register has no meaning in AC'97 audio protocol*

|              |    |    |    |             |    |    |    |             |    |     |            |    |    |    |    |
|--------------|----|----|----|-------------|----|----|----|-------------|----|-----|------------|----|----|----|----|
| 31           | 30 | 29 | 28 | 27          | 26 | 25 | 24 | 23          | 22 | 21  | 20         | 19 | 18 | 17 | 16 |
| SLOTEN[15:0] |    |    |    |             |    |    |    |             |    |     |            |    |    |    |    |
| rw           | rw | rw | rw | rw          | rw | rw | rw | rw          | rw | rw  | rw         | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11          | 10 | 9  | 8  | 7           | 6  | 5   | 4          | 3  | 2  | 1  | 0  |
| Reserved     |    |    |    | NBSLOT[3:0] |    |    |    | SLOTSZ[1:0] |    | Res | FBOFF[4:0] |    |    |    |    |
|              |    |    |    | rw          | rw | rw | rw | rw          | rw |     | rw         | rw | rw | rw | rw |

Bits 31:16 **SLOTEN[15:0]**: Slot enable. These bits are set and cleared by software.

Each bit of the SLOTEN bits identify a slot position from 0 to 15 (maximum 16 slots)

0: Inactive slot.

1: Active slot.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 mode.

Bits 15:12 Reserved, always read as 0.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame. These bits are set and cleared by software.

The value set in these bits register represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.

The number of slots should be even if bit FSDEF in the SAI\_AFRCCR register is set.

If the size is greater than the data size, the remaining bits are forced to 0 if bit TRIS in the SAI\_xCR1 register is clear, otherwise they are forced to 0 if the next slot is active or the SD line is forced to HI-Z if the next slot is inactive and bit TRIS = 1.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 omode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI\_ACR1 register).

01: 16-bit

10: 32-bit

11: Reserved

The slot size must be greater or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 mode.

Bit 1 Reserved, always read as 0.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in these bits represents the position of the first data transfer bit in the slot. It represents an offset value. During this offset phase 0 value are sent on the data line for transmission mode. For reception mode, the received bit are discarded during the offset phase.

These bits must be set when the audio block is disabled.

They are ignored in AC'97 mode.

### 29.17.5 SAI x interrupt mask register (SAI\_xIM) where x is A or B

Address offset: block A: 0x014

Address offset: block B: 0x034

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |              |              |             |            |              |                   |              |
|----------|----|----|----|----|----|----|----|----|--------------|--------------|-------------|------------|--------------|-------------------|--------------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22           | 21           | 20          | 19         | 18           | 17                | 16           |
| Reserved |    |    |    |    |    |    |    |    |              |              |             |            |              |                   |              |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6            | 5            | 4           | 3          | 2            | 1                 | 0            |
| Reserved |    |    |    |    |    |    |    |    | LFSDETI<br>E | AFSDETI<br>E | CNRDY<br>IE | FREQI<br>E | WCKC<br>FGIE | MUT<br>EDET<br>IE | OVRU<br>DRIE |
|          |    |    |    |    |    |    |    |    | rw           | rw           | rw          | rw         | rw           | rw                | rw           |

Bits 31:7 Reserved, always read as 0.

Bit 6 **LFSDETI**: Late frame synchronization detection interrupt enable. This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI\_ASIR register.

This bit has no meaning in AC'97 mode. It has no meaning also if the audio block is master.

Bit 5 **AFSDETI**: Anticipated frame synchronization detection interrupt enable. This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the AFSDET bit in the SAI\_ASIR register is set.

This bit has no meaning in AC'97 mode. It has no meaning also if the audio block is master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (ac'97). This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the codec connected on this line is ready or not. If not, the flag CNRDY in the SAI\_ASIR register is set and an interruption is generated.

This bit has a meaning only if the AC97 mode is selected (bit PRTCFG[1:0]) and the audio block is a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable. This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the FREQ bit in the SAI\_ASIR register is set.

In receiver mode, the bit MODE must be configured before setting bit FREQIE to avoid a parasitic interruption since the audio block is a transmitter (default setting).

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable. This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

This bit is considered only if the audio block is configured as master (MODE[1] = 0 in the SAI\_ACR1 register) and bit NODIV = 0 in the SAI\_xCR1 register.

It generates an interrupt if the flag WCKCFG in the SAI\_ASR register is set.

*Note: This bit is used only in free protocol mode and has no meaning for other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable. This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI\_ASR register is set.

This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable. This bit is set and cleared by software.

0: Interrupt is disabled

1: Interrupt is enabled

When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI\_ASR register is set.

### 29.17.6 SAI x status register (SAI\_xSR) where x is A or B

Address offset: block A: 0x018

Address offset: block B: 0x038

Reset value: 0x0000 0008

|          |    |    |    |    |    |    |    |    |        |        |       |      |        |             |        |
|----------|----|----|----|----|----|----|----|----|--------|--------|-------|------|--------|-------------|--------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22     | 21     | 20    | 19   | 18     | 17          | 16     |
| Reserved |    |    |    |    |    |    |    |    |        |        |       |      | FLTH   |             |        |
|          |    |    |    |    |    |    |    |    |        |        |       |      | r      | r           | r      |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6      | 5      | 4     | 3    | 2      | 1           | 0      |
| Reserved |    |    |    |    |    |    |    |    | LFSDET | AFSDet | CNRDY | FREQ | WCKCFG | MUTED<br>ET | OVRUDR |
|          |    |    |    |    |    |    |    |    | r      | r      | r     | r    | r      | r           | r      |

Bits 31:19 Reserved, always read as 0.

Bits 18:16 **FLTH**: FIFO level threshold. This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

If SAI block is configured as transmitter:

000: FIFO\_empty

001: FIFO  $\leq \frac{1}{4}$  but not empty

010:  $\frac{1}{4} < \text{FIFO} \leq \frac{1}{2}$

011:  $\frac{1}{2} < \text{FIFO} \leq \frac{3}{4}$

100:  $\frac{3}{4} < \text{FIFO}$  but not full

101: FIFO full

If SAI block is configured as receiver:

000: FIFO\_empty

001: FIFO  $< \frac{1}{4}$  but not empty

010:  $\frac{1}{4} \leq \text{FIFO} < \frac{1}{2}$

011:  $\frac{1}{2} \leq \text{FIFO} < \frac{3}{4}$

100:  $\frac{3}{4} \leq \text{FIFO}$  but not full

101: FIFO full

Bits 15:7 Reserved, always read as 0.

Bit 6 **LFSDET**: Late frame synchronization detection. This bit is read only.

0: No error.

1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in Slave mode.

It is not used in AC'97 mode.

It may generate an interrupt if bit LFSDETIE in the SAI\_xIM register is set.

This flag is cleared when the software sets bit CLFSDET in the SAI\_xCLRFR register

Bit 5 **AFSDET**: Anticipated frame synchronization detection. This bit is read only.

0: No error.

1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in Slave mode.

It is not used in AC'97.

It may generate an interrupt if bit AFSDETIE in the SAI\_xIM register is set.

This flag is cleared when the software sets bit CAFSDET in the SAI\_xCLRFR register

- Bit 4 **CNRDY**: Codec not ready. This bit is read only.
- 0: The external AC'97 codec is ready
  - 1: The external AC'97 codec is not ready
- This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register and is configured in receiver mode.
- It may generate an interrupt if bit CNRDYIE in the SAI\_xIM register is set.
- This flag is cleared when the software sets bit CCNRDY in the SAI\_xCLRFR register
- Bit 3 **FREQ**: FIFO request. This bit is read only.
- 0: No FIFO request.
  - 1: FIFO request to read or to write the SAI\_xDR.
- The request depends on the audio block configuration.
- If configured in transmission, the FIFO request concerns a write request operation in the SAI\_xDR.
- If configured in reception, the FIFO request concerns a read request operation from the SAI\_xDR.
- This flag can generate an interrupt if bit FREQIE in the SAI\_xIM register is set.
- Bit 2 **WCKCFG**: Wrong clock configuration flag. This bit is read only.
- 0: The clock configuration is correct
  - 1: The clock configuration does not respect the rule concerning the frame length specification defined in [Section 29.7](#) (configuration of FRL[7:0] bit in the SAI\_x FRCR register)
- This bit is used only when the audio block is master (MODE[1] = 0 in the SAI\_xCR1 register) and when NODIV = 0 in the SAI\_xCR1 register.
- It may generate an interrupt if bit WCKCFGIE in the SAI\_xIM register is set.
- This flag is cleared when the software sets bit CWCKCFG in the SAI\_xCLRFR register
- Bit 1 **MUTEDET**: Mute detection. This bit is read only.
- 0: No MUTE detection on the SD input line
  - 1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame
- This flag is set if consecutive 0 values are received in each slot of an audio frame and for a consecutive number of audio frames (set in the MUTEcnt bit in the SAI\_xCR2 register).
- It may generate an interrupt if bit MUTEDETIE in the SAI\_xIM register is set.
- This flag is cleared when the software sets bit CMUTEDET in the SAI\_xCLRFR register.
- Bit 0 **OVRUDR**: Overrun / underrun. This bit is read only.
- 0: No overrun/underrun error.
  - 1: Overrun/underrun error detection.
- The overrun condition can occur only when the audio block is configured in reception.
- The underrun condition can occur only when the audio block is configured in transmission.
- It may generate an interrupt if bit OVRUDRIE in the SAI\_xIM register is set.
- This flag is cleared when the software set bit COVRUDR bit in the SAI\_xCLRFR register.

### 29.17.7 SAI x clear flag register (SAI\_xCLRFR) where X is A or B

Address offset: block A: 0x01C

Address offset: block B: 0x03C

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |         |         |        |          |         |          |         |
|----------|----|----|----|----|----|----|----|----|---------|---------|--------|----------|---------|----------|---------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22      | 21      | 20     | 19       | 18      | 17       | 16      |
| Reserved |    |    |    |    |    |    |    |    |         |         |        |          |         |          |         |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6       | 5       | 4      | 3        | 2       | 1        | 0       |
| Reserved |    |    |    |    |    |    |    |    | CLFSDET | CAFSDET | CCNRDY | Reserved | CWCKCFG | CMUTEDET | COVRUDR |
|          |    |    |    |    |    |    |    |    | rw      | rw      | rw     |          | rw      | rw       | rw      |

Bits 31:7 Reserved, always read as 0.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag. This bit is write only.

Writing 1 in this bit clears the flag LFSDET in the SAI\_xSR register.

It is not used in AC'97.

Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag. This bit is write only.

Writing 1 in this bit clears the flag AFSDET in the SAI\_xSR register.

It is not used in AC'97.

Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear codec not ready flag. This bit is write only.

Writing 1 in this bit clears the flag CNRDY in the SAI\_xSR register.

This bit is used only when the AC'97 audio protocol is selected in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 3 Reserved, always read as 0.

Bit 2 **CWCKCFG**: Clear wrong clock configuration flag. This bit is write only.

Writing 1 in this bit clears the flag WCKCFG in the SAI\_xSR register.

This bit is used only when the audio block is set as master (MODE[1] = 0 in the SAI\_ACR1 register) and bit NODIV = 0 in the SAI\_xCR1 register.

Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag. This bit is write only.

Writing 1 in this bit clears the flag MUTEDET in the SAI\_xSR register.

Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun. This bit is write only.

Writing 1 in this bit clears the flag OVRUDR in the SAI\_xSR register.

Reading this bit always returns the value 0.

### 29.17.8 SAI x data register (SAI\_xDR) where x is A or B

Address offset: block A: 0x020

Address offset: block B: 0x040

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

| DATA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **DATA[31:0]**: Data

A write into this register has the effect of loading the FIFO if the FIFO is not full.

A read from this register has to effect of draining-up the FIFO if the FIFO is not empty.

### 29.17.9 SAI register map

The following table summarizes the SAI registers.

**Table 133. SAI register map and reset values**

| Offset                 | Register and reset value | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23          | 22 | 21        | 20    | 19    | 18           | 17         | 16          | 15        | 14     | 13       | 12              | 11              | 10    | 9          | 8       | 7   | 6        | 5                | 4 | 3         | 2 | 1 | 0 |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 30 Universal synchronous asynchronous receiver transmitter (USART)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 30.1 USART introduction

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a fractional baud rate generator.

It supports synchronous one-way communication and half-duplex single wire communication. It also supports the LIN (local interconnection network), Smartcard Protocol and IrDA (infrared data association) SIR ENDEC specifications, and modem operations (CTS/RTS). It allows multiprocessor communication.

High speed data communication is possible by using the DMA for multibuffer configuration.

### 30.2 USART main features

- Full duplex, asynchronous communications
- NRZ standard format (Mark/Space)
- Configurable oversampling method by 16 or by 8 to give flexibility between speed and clock tolerance
- Fractional baud rate generator systems
  - Common programmable transmit and receive baud rate (refer to the datasheets for the value of the baud rate at the maximum APB frequency).
- Programmable data word length (8 or 9 bits)
- Configurable stop bits - support for 1 or 2 stop bits
- LIN Master Synchronous Break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- Transmitter clock output for synchronous transmission
- IrDA SIR encoder decoder
  - Support for 3/16 bit duration for normal mode
- Smartcard emulation capability
  - The Smartcard interface supports the asynchronous protocol Smartcards as defined in the ISO 7816-3 standards
  - 0.5, 1.5 stop bits for Smartcard operation
- Single-wire half-duplex communication
- Configurable multibuffer communication using DMA (direct memory access)
  - Buffering of received/transmitted bytes in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver

- Transfer detection flags:
  - Receive buffer full
  - Transmit buffer empty
  - End of transmission flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Four error detection flags:
  - Overrun error
  - Noise detection
  - Frame error
  - Parity error
- Ten interrupt sources with flags:
  - CTS changes
  - LIN break detection
  - Transmit data register empty
  - Transmission complete
  - Receive data register full
  - Idle line received
  - Overrun error
  - Framing error
  - Noise error
  - Parity error
- Multiprocessor communication - enter into mute mode if address match does not occur
- Wake up from mute mode (by idle line detection or address mark detection)
- Two receiver wake-up modes: Address bit (MSB, 9<sup>th</sup> bit), Idle line

### 30.3 USART functional description

The interface is externally connected to another device by three pins (see [Figure 296](#)). Any USART bidirectional communication requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

**RX:** Receive Data Input is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

**TX:** Transmit Data Output. When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In single-wire and smartcard modes, this I/O is used to transmit and receive the data (at USART level, data are then received on SW\_RX).

Through these pins, serial data is transmitted and received in normal USART mode as frames comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (8 or 9 bits) least significant bit first
- 0.5, 1, 1.5, 2 Stop bits indicating that the frame is complete
- This interface uses a fractional baud rate generator - with a 12-bit mantissa and 4-bit fraction
- A status register (USART\_SR)
- Data Register (USART\_DR)
- A baud rate register (USART\_BRR) - 12-bit mantissa and 4-bit fraction.
- A Guardtime Register (USART\_GTPR) in case of Smartcard mode.

Refer to [Section 30.6: USART registers on page 1010](#) for the definitions of each bit.

The following pin is required to interface in synchronous mode:

- **CK:** Transmitter clock output. This pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel data can be received synchronously on RX. This can be used to control peripherals that have shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable. In smartcard mode, CK can provide the clock to the smartcard.

The following pins are required in Hardware flow control mode:

- **CTS:** Clear To Send blocks the data transmission at the end of the current transfer when high
- **RTS:** Request to send indicates that the USART is ready to receive a data (when low).

**Figure 296. USART block diagram**

### 30.3.1 USART character description

Word length may be selected as being either 8 or 9 bits by programming the M bit in the USART\_CR1 register (see [Figure 297](#)).

The TX pin is in low state during the start bit. It is in high state during the stop bit.

An **Idle character** is interpreted as an entire frame of “1”s followed by the start bit of the next frame which contains data (The number of “1” ‘s includes the number of stop bits).

A **Break character** is interpreted on receiving “0”s for a frame period. At the end of the break frame the transmitter inserts either 1 or 2 stop bits (logic “1” bit) to acknowledge the start bit.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.

**Figure 297. Word length programming**

### 30.3.2 Transmitter

The transmitter can send data words of either 8 or 9 bits depending on the M bit status. When the transmit enable bit (TE) is set, the data in the transmit shift register is output on the TX pin and the corresponding clock pulses are output on the CK pin.

#### Character transmission

During an USART transmission, data shifts out least significant bit first on the TX pin. In this mode, the USART\_DR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see [Figure 296](#)).

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by USART: 0.5, 1, 1.5 and 2 stop bits.

*Note: The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are lost.*

*An idle frame is sent after the TE bit is enabled.*

#### Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in Control register 2, bits 13,12.

- **1 stop bit:** This is the default value of number of stop bits.
- **2 Stop bits:** This is supported by normal USART, single-wire and modem modes.
- **0.5 stop bit:** To be used when receiving data in Smartcard mode.
- **1.5 stop bits:** To be used when transmitting and receiving data in Smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits followed by the configured number of stop bits (when m = 0) and 11 low bits followed by the configured number of stop bits (when m = 1). It is not possible to transmit long breaks (break of length greater than 10/11 low bits).

Figure 298. Configurable stop bits

Procedure:

1. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
2. Program the M bit in USART\_CR1 to define the word length.
3. Program the number of stop bits in USART\_CR2.
4. Select DMA enable (DMAT) in USART\_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in multibuffer communication.
5. Select the desired baud rate using the USART\_BRR register.
6. Set the TE bit in USART\_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART\_DR register (this clears the TXE bit). Repeat this for each data to be transmitted in case of single buffer.
8. After writing the last data into the USART\_DR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the USART is disabled or enters the Halt mode to avoid corrupting the last transmission.

### Single byte communication

Clearing the TXE bit is always performed by a write to the data register.

The TXE bit is set by hardware and it indicates:

- The data has been moved from TDR to the shift register and the data transmission has started.
- The TDR register is empty.
- The next data can be written in the USART\_DR register without overwriting the previous data.

This flag generates an interrupt if the TXEIE bit is set.

When a transmission is taking place, a write instruction to the USART\_DR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission.

When no transmission is taking place, a write instruction to the USART\_DR register places the data directly in the shift register, the data transmission starts, and the TXE bit is immediately set.

If a frame is transmitted (after the stop bit) and the TXE bit is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the USART\_CR1 register.

After writing the last data into the USART\_DR register, it is mandatory to wait for TC=1 before disabling the USART or causing the microcontroller to enter the low-power mode (see [Figure 299: TC/TXE behavior when transmitting](#)).

The TC bit is cleared by the following software sequence:

1. A read from the USART\_SR register
2. A write to the USART\_DR register

**Note:** *The TC bit can also be cleared by writing a '0' to it. This clearing sequence is recommended only for Multibuffer communication.*

**Figure 299. TC/TXE behavior when transmitting**

## Break characters

Setting the SBK bit transmits a break character. The break frame length depends on the M bit (see [Figure 297](#)).

If the SBK bit is set to '1' a break character is sent on the TX line after completing the current character transmission. This bit is reset by hardware when the break character is completed (during the stop bit of the break character). The USART inserts a logic 1 bit at the end of the last break frame to guarantee the recognition of the start bit of the next frame.

**Note:** *If the software resets the SBK bit before the commencement of break transmission, the break character is not transmitted. For two consecutive breaks, the SBK bit should be set after the stop bit of the previous break.*

### Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

### 30.3.3 Receiver

The USART can receive data words of either 8 or 9 bits depending on the M bit in the USART\_CR1 register.

#### Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0 X 0 0 0.

**Figure 300. Start bit detection when oversampling by 16 or 8**

**Note:** If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1) if the three sampled bits are at 0 (first sampling on the third, fifth and seventh bit finds the three bits at 0 and second sampling on the eighth, ninth and tenth bit also finds the three bits at 0).

The start bit is validated (RXNE flag set, interrupt generated if RXNEIE=1) but the NE noise flag is set if, for both samplings, at least two out of the three sampled bits are at 0 (sampling on the third, fifth and seventh bit and sampling on the eighth, ninth and tenth bit). If this

condition is not met, the start detection aborts and the receiver returns to the idle state (no flag is set).

If, for one of the samplings (on the third, fifth and seventh bit, or on the eighth, ninth and tenth bit), two out of the three bits are found at 0, the start bit is validated but the NE noise flag bit is set.

### Character reception

During an USART reception, data shifts in least significant bit first through the RX pin. In this mode, the USART\_DR register consists of a buffer (RDR) between the internal bus and the received shift register.

Procedure:

1. Enable the USART by writing the UE bit in USART\_CR1 register to 1.
2. Program the M bit in USART\_CR1 to define the word length.
3. Program the number of stop bits in USART\_CR2.
4. Select DMA enable (DMAR) in USART\_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication. STEP 3
5. Select the desired baud rate using the baud rate register USART\_BRR
6. Set the RE bit USART\_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- The RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXNEIE bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In multibuffer, RXNE is set after every byte received and is cleared by the DMA read to the Data Register.
- In single buffer mode, clearing the RXNE bit is performed by a software read to the USART\_DR register. The RXNE flag can also be cleared by writing a zero to it. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.

*Note:* The RE bit should not be reset while receiving data. If the RE bit is disabled during reception, the reception of the current byte is aborted.

### Break character

When a break character is received, the USART handles it as a framing error.

### Idle character

When an idle frame is detected, there is the same procedure as a data received character plus an interrupt if the IDLEIE bit is set.

### Overrun error

An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared.

The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content is not lost. The previous data is available when a read to USART\_DR is performed.
- The shift register is overwritten. After that point, any data received during overrun is lost.
- An interrupt is generated if either the RXNEIE bit is set or both the EIE and DMAR bits are set.
- The ORE bit is reset by a read to the USART\_SR register followed by a USART\_DR register read operation.

*Note:* The ORE bit, when set, indicates that at least 1 data has been lost. There are two possibilities:

- if RXNE=1, then the last valid data is stored in the receive register RDR and can be read,
- if RXNE=0, then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received. It may also occur when the new data is received during the reading sequence (between the USART\_SR register read access and the USART\_DR read access).

### Selecting the proper oversampling method

The receiver implements different user-configurable oversampling techniques (except in synchronous mode) for data recovery by discriminating between valid incoming data and noise.

The oversampling method can be selected by programming the OVER8 bit in the USART\_CR1 register and can be either 16 or 8 times the baud rate clock ([Figure 301](#) and [Figure 302](#)).

Depending on the application:

- select oversampling by 8 (OVER8=1) to achieve higher speed (up to  $f_{PCLK}/8$ ). In this case the maximum receiver tolerance to clock deviation is reduced (refer to [Section 30.3.5: USART receiver tolerance to clock deviation on page 991](#))
- select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum  $f_{PCLK}/16$

Figure 302. Data sampling when oversampling by 8

Table 134. Noise detection from sampled data

| Sampled value | NE status | Received bit value |
|---------------|-----------|--------------------|
| 000           | 0         | 0                  |
| 001           | 1         | 0                  |
| 010           | 1         | 0                  |
| 011           | 1         | 1                  |
| 100           | 1         | 0                  |
| 101           | 1         | 1                  |
| 110           | 1         | 1                  |
| 111           | 0         | 1                  |

### Framing error

A framing error is detected when:

The stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- The FE bit is set by hardware
- The invalid data is transferred from the Shift register to the USART\_DR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART\_CR3 register.

The FE bit is reset by a USART\_SR register read operation followed by a USART\_DR register read operation.

### Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of Control Register 2 - it can be either 1 or 2 in normal mode and 0.5 or 1.5 in Smartcard mode.

1. **0.5 stop bit (reception in Smartcard mode):** No sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
2. **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.
3. **1.5 stop bits (Smartcard mode):** When transmitting in smartcard mode, the device must check that the data is correctly sent. Thus the receiver block must be enabled (RE =1 in the USART\_CR1 register) and the stop bit is checked to test if the smartcard has detected a parity error. In the event of a parity error, the smartcard forces the data signal low during the sampling - NACK signal-, which is flagged as a framing error. Then, the FE flag is set with the RXNE at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be decomposed into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through. Refer to [Section 30.3.11: Smartcard on page 1000](#) for more details.
4. **2 stop bits:** Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. If a framing error is detected during the first stop bit the framing error flag is set. The second stop bit is not checked for framing error. The RXNE flag is set at the end of the first stop bit.

### 30.3.4 Fractional baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the Mantissa and Fraction values of USARTDIV.

#### Equation 1: Baud rate for standard USART (SPI mode included)

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{8 \times (2 - \text{OVER8}) \times \text{USARTDIV}}$$

#### Equation 2: Baud rate in Smartcard, LIN and IrDA modes

$$\text{Tx/Rx baud} = \frac{f_{\text{CK}}}{16 \times \text{USARTDIV}}$$

USARTDIV is an unsigned fixed point number that is coded on the USART\_BRR register.

- When OVER8=0, the fractional part is coded on 4 bits and programmed by the DIV\_fraction[3:0] bits in the USART\_BRR register
- When OVER8=1, the fractional part is coded on 3 bits and programmed by the DIV\_fraction[2:0] bits in the USART\_BRR register, and bit DIV\_fraction[3] must be kept cleared.

*Note:* The baud counters are updated to the new value in the baud registers after a write operation to USART\_BRR. Hence the baud rate register value should not be changed during communication.

**How to derive USARTDIV from USART\_BRR register values when OVER8=0****Example 1:**

If DIV\_Mantissa = 0d27 and DIV\_Fraction = 0d12 (USART\_BRR = 0x1BC), then

Mantissa (USARTDIV) = 0d27

Fraction (USARTDIV) =  $12/16 = 0d0.75$

Therefore USARTDIV = 0d27.75

**Example 2:**

To program USARTDIV = 0d25.62

This leads to:

$DIV\_Fraction = 16 * 0d0.62 = 0d9.92$

The nearest real number is 0d10 = 0xA

$DIV\_Mantissa = \text{mantissa}(0d25.620) = 0d25 = 0x19$

Then, USART\_BRR = 0x19A hence USARTDIV = 0d25.625

**Example 3:**

To program USARTDIV = 0d50.99

This leads to:

$DIV\_Fraction = 16 * 0d0.99 = 0d15.84$

The nearest real number is 0d16 = 0x10 => overflow of DIV\_frac[3:0] => carry must be added up to the mantissa

$DIV\_Mantissa = \text{mantissa}(0d50.990 + \text{carry}) = 0d51 = 0x33$

Then, USART\_BRR = 0x330 hence USARTDIV = 0d51.000

**How to derive USARTDIV from USART\_BRR register values when OVER8=1****Example 1:**

If DIV\_Mantissa = 0x27 and DIV\_Fraction[2:0] = 0d6 (USART\_BRR = 0x1B6), then

Mantissa (USARTDIV) = 0d27

Fraction (USARTDIV) =  $6/8 = 0d0.75$

Therefore USARTDIV = 0d27.75

**Example 2:**

To program USARTDIV = 0d25.62

This leads to:

$DIV\_Fraction = 8 * 0d0.62 = 0d4.96$

The nearest real number is 0d5 = 0x5

$DIV\_Mantissa = \text{mantissa}(0d25.620) = 0d25 = 0x19$

Then, USART\_BRR = 0x195 => USARTDIV = 0d25.625

**Example 3:**

To program USARTDIV = 0d50.99

This leads to:

DIV\_Fraction =  $8 \times 0d0.99 = 0d7.92$

The nearest real number is 0d8 = 0x8 => overflow of the DIV\_frac[2:0] => carry must be added up to the mantissa

DIV\_Mantissa = mantissa (0d50.990 + carry) = 0d51 = 0x33

Then, USART\_BRR = 0x0330 => USARTDIV = 0d51.000

**Table 135. Error calculation for programmed baud rates at  $f_{PCLK} = 8$  MHz or  $f_{PCLK} = 12$  MHz, oversampling by 16<sup>(1)</sup>**

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.
2. Only USART1 and USART6 are clocked with PCLK2. Other USARTs are clocked with PCLK1. Refer to the device datasheets for the maximum values for PCLK1 and PCLK2.

| 17.                         | 10.5 MBps | N.A                 | N.A                                        | N.A                                        | 10.5 MBps           | 1                                          | 0       |

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.
2. Only USART1 and USART6 are clocked with PCLK2. Other USARTs are clocked with PCLK1. Refer to the device datasheets for the maximum values for PCLK1 and PCLK2.

### 30.3.5 USART receiver tolerance to clock deviation

The USART asynchronous receiver works correctly only if the total clock system deviation is smaller than the USART receiver's tolerance. The causes which contribute to the total deviation are:

- DTRA: Deviation due to the transmitter error (which also includes the deviation of the transmitter's local oscillator)
- DQUANT: Error due to the baud rate quantization of the receiver
- DREC: Deviation of the receiver's local oscillator
- DTCL: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

$DTRA + DQUANT + DREC + DTCL < \text{USART receiver's tolerance}$

The USART receiver's tolerance to properly receive data is equal to the maximum tolerated deviation and depends on the following choices:

- 10- or 11-bit character length defined by the M bit in the USART\_CR1 register
- oversampling by 8 or 16 defined by the OVER8 bit in the USART\_CR1 register
- use of fractional baud rate or not
- use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART\_CR3 register

**Table 145. USART receiver's tolerance when DIV fraction is 0**

| M bit | OVER8 bit = 0 |          | OVER8 bit = 1 |          |
|-------|---------------|----------|---------------|----------|
|       | ONEBIT=0      | ONEBIT=1 | ONEBIT=0      | ONEBIT=1 |
| 0     | 3.75%         | 4.375%   | 2.50%         | 3.75%    |
| 1     | 3.41%         | 3.97%    | 2.27%         | 3.41%    |

**Table 146. USART receiver tolerance when DIV\_Fraction is different from 0**

| M bit | OVER8 bit = 0 |          | OVER8 bit = 1 |          |
|-------|---------------|----------|---------------|----------|
|       | ONEBIT=0      | ONEBIT=1 | ONEBIT=0      | ONEBIT=1 |
| 0     | 3.33%         | 3.88%    | 2%            | 3%       |
| 1     | 3.03%         | 3.53%    | 1.82%         | 2.73%    |

*Note:* The figures specified in [Table 145](#) and [Table 146](#) may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M=0 (11-bit times when M=1).

### 30.3.6 Multiprocessor communication

There is a possibility of performing multiprocessor communication with the USART (several USARTs connected in a network). For instance one of the USARTs can be the master, its TX output is connected to the RX input of the other USART. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In mute mode:

- None of the reception status bits can be set.
- All the receive interrupts are inhibited.
- The RWU bit in USART\_CR1 register is set to 1. RWU can be controlled automatically by hardware or written by the software under certain conditions.

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART\_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

#### Idle line detection (WAKE=0)

The USART enters mute mode when the RWU bit is written to 1.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the USART\_SR register. RWU can also be written to 0 by software.

An example of mute mode behavior using Idle line detection is given in [Figure 303](#).

Figure 303. Mute mode using Idle line detection

### Address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a '1' else they are considered as data. In an address byte, the address of the targeted receiver is put on the 4 LSB. This 4-bit word is compared by the receiver with its own address which is programmed in the ADDR bits in the USART\_CR2 register.

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt nor DMA request is issued as the USART would have entered mute mode.

It exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE bit is set for the address character since the RWU bit has been cleared.

The RWU bit can be written to as 0 or 1 when the receiver buffer contains no data (RXNE=0 in the USART\_SR register). Otherwise the write attempt is ignored.

An example of mute mode behavior using address mark detection is given in [Figure 304](#).

Figure 304. Mute mode using address mark detection

### 30.3.7 Parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART\_CR1 register. Depending on the frame length defined by the M bit, the possible USART frame formats are as listed in [Table 147](#).

**Table 147. Frame formats**

| M bit | PCE bit | USART frame <sup>(1)</sup> |
|-------|---------|----------------------------|
| 0     | 0       | SB   8 bit data   STB      |
| 0     | 1       | SB   7-bit data   PB   STB |
| 1     | 0       | SB   9-bit data   STB      |
| 1     | 1       | SB   8-bit data PB   STB   |

1. Legends: SB: start bit, STB: stop bit, PB: parity bit.

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

E.g.: data=00110101; 4 bits set => parity bit is 0 if even parity is selected (PS bit in USART\_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 7 or 8 LSB bits (depending on whether M is equal to 0 or 1) and the parity bit.

E.g.: data=00110101; 4 bits set => parity bit is 1 if odd parity is selected (PS bit in USART\_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART\_SR register and an interrupt is generated if PEIE is set in the USART\_CR1 register. The PE flag is cleared by a software sequence (a read from the status register followed by a read or write access to the USART\_DR data register).

*Note:* In case of wake-up by an address mark: the MSB bit of the data is taken into account to identify an address but not the parity bit. And the receiver does not check the parity of the address data (PE is not set in case of a parity error).

#### Parity generation in transmission

If the PCE bit is set in USART\_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

*Note:* The software routine that manages the transmission can activate the software sequence which clears the PE flag (a read from the status register followed by a read or write access to the data register). When operating in half-duplex mode, depending on the software, this can cause the PE flag to be unexpectedly cleared.

### 30.3.8 LIN (local interconnection network) mode

The LIN mode is selected by setting the LINEN bit in the USART\_CR2 register. In LIN mode, the following bits must be kept cleared:

- STOP[1:0] and CLKEN in the USART\_CR2 register
- SCEN, HDSEL and IREN in the USART\_CR3 register.

#### LIN transmission

The same procedure explained in [Section 30.3.2](#) has to be applied for LIN Master transmission than for normal USART transmission with the following differences:

- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBK bit sends 13 '0 bits as a break character. Then a bit of value '1 is sent to allow the next start detection.

#### LIN reception

A break detection circuit is implemented on the USART interface. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART\_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART\_CR2) or 11 (when LBDL=1 in USART\_CR2) consecutive bits are detected as '0, and are followed by a delimiter character, the LBD flag is set in USART\_SR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a '1 is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (stop bit detected at '0, which is the case for any break frame), the receiver stops until the break detection circuit receives either a '1, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the [Figure 305: Break detection in LIN mode \(11-bit break length - LBDL bit is set\) on page 996](#).

Examples of break frames are given on [Figure 306: Break detection in LIN mode vs. Framing error detection on page 997](#).

Figure 305. Break detection in LIN mode (11-bit break length - LBDL bit is set)

Case 1: break signal not long enough => break discarded, LBD is not set

Case 2: break signal just long enough => break detected, LBD is set

Case 3: break signal long enough => break detected, LBD is set

MSv40883V1

Figure 306. Break detection in LIN mode vs. Framing error detection

### 30.3.9 USART synchronous mode

The synchronous mode is selected by writing the CLKEN bit in the USART\_CR2 register to 1. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- SCEN, HDSEL and IREN bits in the USART\_CR3 register.

The USART allows the user to control a bidirectional synchronous serial communications in master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART\_CR2 register clock pulses are generated or not during the last valid data bit (address mark). The CPOL bit in the USART\_CR2 register allows the user to select the clock polarity, and the CPHA bit in the USART\_CR2 register allows the user to select the phase of the external clock (see [Figure 307](#), [Figure 308](#) & [Figure 309](#)).

During the Idle state, preamble and send break, the external CK clock is not activated.

In synchronous mode the USART transmitter works exactly like in asynchronous mode. But as CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In this mode the USART receiver works in a different manner compared to the asynchronous mode. If RE=1, the data is sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).

**Note:** The CK pin works in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and a data is being transmitted (the data register USART\_DR

has been written). This means that it is not possible to receive a synchronous data without transmitting data.

The LBCL, CPOL and CPHA bits have to be selected when both the transmitter and the receiver are disabled ( $TE=RE=0$ ) to ensure that the clock pulses function correctly. These bits should not be changed while the transmitter or the receiver is enabled.

It is advised that  $TE$  and  $RE$  are set in the same instruction in order to minimize the setup and the hold time of the receiver.

The USART supports master mode only: it cannot receive or send data related to an input clock ( $CK$  is always an output).

**Figure 307. USART example of synchronous transmission**

**Figure 308. USART data clock timing diagram (M=0)**

Figure 309. USART data clock timing diagram (M=1)

Figure 310. RX data setup/hold time

**Note:** The function of CK is different in Smartcard mode. Refer to the Smartcard mode chapter for more details.

### 30.3.10 Single-wire half-duplex communication

The single-wire half-duplex mode is selected by setting the HDSEL bit in the USART\_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART\_CR2 register,
- SCEN and IREN bits in the USART\_CR3 register.

The USART can be configured to follow a single-wire half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and full-duplex communication is made with a control bit 'HALF DUPLEX SEL' (HDSEL in USART\_CR3).

As soon as HDSEL is written to 1:

- the TX and RX lines are internally connected
- the RX pin is no longer used
- the TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as floating input (or output high open-drain) when not driven by the USART.

Apart from this, the communications are similar to what is done in normal USART mode. The conflicts on the line must be managed by the software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continue to occur as soon as a data is written in the data register while the TE bit is set.

### 30.3.11 Smartcard

The Smartcard mode is selected by setting the SCEN bit in the USART\_CR3 register. In smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART\_CR2 register,
- HDSEL and IREN bits in the USART\_CR3 register.

Moreover, the CLKEN bit may be set in order to provide a clock to the smartcard.

The Smartcard interface is designed to support asynchronous protocol Smartcards as defined in the ISO 7816-3 standard. The USART should be configured as:

- 8 bits plus parity: where M=1 and PCE=1 in the USART\_CR1 register
- 1.5 stop bits when transmitting and receiving: where STOP=11 in the USART\_CR2 register.

*Note:* It is also possible to choose 0.5 stop bit for receiving but it is recommended to use 1.5 stop bits for both transmitting and receiving to avoid switching between the two configurations.

Figure 311 shows examples of what can be seen on the data line with and without parity error.

**Figure 311. ISO 7816-3 asynchronous protocol**

When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open-drain.

Smartcard is a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts

shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.

- If a parity error is detected during reception of a frame programmed with a 0.5 or 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to USART has not been correctly received. This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The application can handle re-sending of data according to the protocol. A parity error is 'NACK'ed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted.
- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the guard time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the guard time counter reaches the programmed value TC is asserted high.
- The de-assertion of TC flag is unaffected by Smartcard mode.
- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.
- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

**Note:** A break character is not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 312 details how the NACK signal is sampled by the USART. In this example the USART is transmitting a data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.

**Figure 312. Parity error detection using the 1.5 stop bits**

The USART can provide a clock to the smartcard through the CK output. In smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the

prescaler register USART\_GTPR. CK frequency can be programmed from  $f_{CK}/2$  to  $f_{CK}/62$ , where  $f_{CK}$  is the peripheral input clock.

### 30.3.12 IrDA SIR ENDEC block

The IrDA mode is selected by setting the IREN bit in the USART\_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART\_CR2 register,
- SCEN and HDSEL bits in the USART\_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see [Figure 313](#)).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to USART. The decoder input is normally HIGH (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (i.e. the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not encoded by IrDA. While receiving data, transmission should be avoided as the data to be transmitted could be corrupted.
- A '0 is transmitted as a high pulse and a '1 is transmitted as a '0. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see [Figure 314](#)).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41  $\mu$ s. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the IrDA low-power Baud Register, USART\_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods are accepted as a pulse. The IrDA encoder/decoder does not work when PSC = 0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the STOP bits in the USART\_CR2 register must be configured to "1 stop bit".

## IrDA low-power mode

### Transmitter:

In low-power mode the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally this value is 1.8432 MHz ( $1.42 \text{ MHz} < \text{PSC} < 2.12 \text{ MHz}$ ). A low-power mode programmable divisor divides the system clock to achieve this value.

### Receiver:

Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than  $1/\text{PSC}$ . A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in USART\_GTPR).

**Note:** A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.

The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).

Figure 313. IrDA SIR ENDEC- block diagram

Figure 314. IrDA data modulation (3/16) -Normal mode

### 30.3.13 Continuous communication using DMA

The USART is capable of continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

#### Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART\_CR3 register. Data is loaded from a SRAM area configured using the DMA peripheral (refer to the DMA specification) to the USART\_DR register whenever the TXE bit is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART\_DR register address in the DMA control register to configure it as the destination of the transfer. The data are moved to this address from memory after each TXE event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data are loaded into the USART\_DR register from this memory area after each TXE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC bit in the SR register by writing 0 to it.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA\_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or entering the Stop mode. The software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the last frame's end of transmission.

Figure 315. Transmission using DMA

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART\_CR3 register. Data is loaded from the USART\_DR register to a SRAM area configured using the DMA peripheral (refer to the DMA specification) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART\_DR register address in the DMA control register to configure it as the source of the transfer. The data are moved from this address to the memory after each RXNE event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data are loaded from USART\_DR to this memory area after each RXNE event.
3. Configure the total number of bytes to be transferred in the DMA control register.
4. Configure the channel priority in the DMA control register
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector. The DMAR bit should be cleared by software in the USART\_CR3 register during the interrupt subroutine.

Figure 316. Reception using DMA

### Error flagging and interrupt generation in multibuffer communication

In case of multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in case of single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART\_CR3 register), which if set, issues an interrupt after the current byte with either of these errors.

#### 30.3.14 Hardware flow control

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The [Figure 317](#) shows how to connect 2 devices in this mode:

Figure 317. Hardware flow control between 2 USARTs

RTS and CTS flow control can be enabled independently by writing respectively RTSE and CTSE bits to 1 (in the USART\_CR3 register).

### RTS flow control

If the RTS flow control is enabled ( $RTSE=1$ ), then RTS is asserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is deasserted, indicating that the transmission is expected to stop at the end of the current frame. [Figure 318](#) shows an example of communication with RTS flow control enabled.

**Figure 318. RTS flow control**

### CTS flow control

If the CTS flow control is enabled ( $CTSE=1$ ), then the transmitter checks the CTS input before transmitting the next frame. If CTS is asserted (tied low), then the next data is transmitted (assuming that a data is to be transmitted, in other words, if  $TXE=0$ ), else the transmission does not occur. When CTS is deasserted during a transmission, the current transmission is completed before the transmitter stops.

When  $CTSE=1$ , the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART\_CR3 register is set. The figure below shows an example of communication with CTS flow control enabled.

Figure 319. CTS flow control

*Note:* **Special behavior of break frames:** when the CTS flow is enabled, the transmitter does not check the CTS input state to send a break.

## 30.4 USART interrupts

Table 148. USART interrupt requests

| Interrupt event                                                          | Event flag      | Enable control bit |
|--------------------------------------------------------------------------|-----------------|--------------------|
| Transmit Data Register Empty                                             | TXE             | TXEIE              |
| CTS flag                                                                 | CTS             | CTSIE              |
| Transmission Complete                                                    | TC              | TCIE               |
| Received Data Ready to be Read                                           | RXNE            | RXNEIE             |
| Overrun Error Detected                                                   | ORE             |                    |
| Idle Line Detected                                                       | IDLE            | IDLEIE             |
| Parity Error                                                             | PE              | PEIE               |
| Break Flag                                                               | LBD             | LBDIE              |
| Noise Flag, Overrun error and Framing Error in multibuffer communication | NF or ORE or FE | EIE                |

The USART interrupt events are connected to the same interrupt vector (see [Figure 320](#)).

- During transmission: Transmission Complete, Clear to Send or Transmit Data Register empty interrupt.
- While receiving: Idle Line detection, Overrun error, Receive Data register not empty, Parity error, LIN break detection, Noise Flag (only in multi buffer communication) and Framing Error (only in multi buffer communication).

These events generate an interrupt if the corresponding Enable Control Bit is set.

Figure 320. USART interrupt mapping diagram

## 30.5 USART mode configuration

Table 149. USART mode configuration<sup>(1)</sup>

| USART modes                     | USART 1 | USART 2 | USART 3 | UART4 | UART5 | USART 6 |
|---------------------------------|---------|---------|---------|-------|-------|---------|
| Asynchronous mode               | X       | X       | X       | X     | X     | X       |
| Hardware flow control           | X       | X       | X       | NA    | NA    | X       |
| Multibuffer communication (DMA) | X       | X       | X       | X     | X     | X       |
| Multiprocessor communication    | X       | X       | X       | X     | X     | X       |
| Synchronous                     | X       | X       | X       | NA    | NA    | X       |
| Smartcard                       | X       | X       | X       | NA    | NA    | X       |
| Half-duplex (single-wire mode)  | X       | X       | X       | X     | X     | X       |
| IrDA                            | X       | X       | X       | X     | X     | X       |
| LIN                             | X       | X       | X       | X     | X     | X       |

1. X = supported; NA = not applicable.

## 30.6 USART registers

Refer to [Section 1.1: List of abbreviations for registers for registers](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by half-words (16 bits) or words (32 bits).

### 30.6.1 Status register (USART\_SR)

Address offset: 0x00

Reset value: 0x000C0 00C0

|          |    |    |    |    |    |       |       |     |       |       |      |     |    |    |    |
|----------|----|----|----|----|----|-------|-------|-----|-------|-------|------|-----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25    | 24    | 23  | 22    | 21    | 20   | 19  | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |       |       |     |       |       |      |     |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9     | 8     | 7   | 6     | 5     | 4    | 3   | 2  | 1  | 0  |
| Reserved |    |    |    |    |    | CTS   | LBD   | TXE | TC    | RXNE  | IDLE | ORE | NF | FE | PE |
|          |    |    |    |    |    | rc_w0 | rc_w0 | r   | rc_w0 | rc_w0 | r    | r   | r  | r  | r  |

Bits 31:10 Reserved, must be kept at reset value

Bit 9 **CTS**: CTS flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software (by writing it to 0). An interrupt is generated if CTSIE=1 in the USART\_CR3 register.

0: No change occurred on the CTS status line

1: A change occurred on the CTS status line

*Note: This bit is not available for UART4 & UART5.*

Bit 8 **LBD**: LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software (by writing it to 0). An interrupt is generated if LBDIE = 1 in the USART\_CR2 register.

0: LIN Break not detected

1: LIN break detected

*Note: An interrupt is generated when LBD=1 if LBDIE=1*

Bit 7 **TXE**: Transmit data register empty

This bit is set by hardware when the content of the TDR register has been transferred into the shift register. An interrupt is generated if the TXEIE bit =1 in the USART\_CR1 register. It is cleared by a write to the USART\_DR register.

0: Data is not transferred to the shift register

1: Data is transferred to the shift register

*Note: This bit is used during single buffer transmission.*

Bit 6 **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the USART\_CR1 register. It is cleared by a software sequence (a read from the USART\_SR register followed by a write to the USART\_DR register). The TC bit can also be cleared by writing a '0' to it. This clearing sequence is recommended only for multibuffer communication.

0: Transmission is not complete

1: Transmission is complete

Bit 5 **RXNE**: Read data register not empty

This bit is set by hardware when the content of the RDR shift register has been transferred to the USART\_DR register. An interrupt is generated if RXNEIE=1 in the USART\_CR1 register. It is cleared by a read to the USART\_DR register. The RXNE flag can also be cleared by writing a zero to it. This clearing sequence is recommended only for multibuffer communication.

0: Data is not received

1: Received data is ready to be read.

Bit 4 **IDLE**: IDLE line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if the IDLEIE=1 in the USART\_CR1 register. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No Idle Line is detected

1: Idle Line is detected

*Note: The IDLE bit is not set again until the RXNE bit has been set itself (a new idle line occurs).*

**Bit 3 ORE:** Overrun error

This bit is set by hardware when the word currently being received in the shift register is ready to be transferred into the RDR register while RXNE=1. An interrupt is generated if RXNEIE=1 in the USART\_CR1 register. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No Overrun error

1: Overrun error is detected

*Note: When this bit is set, the RDR register content is not lost but the shift register is overwritten. An interrupt is generated on ORE flag in case of Multi Buffer communication if the EIE bit is set.*

**Bit 2 NF:** Noise detected flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No noise is detected

1: Noise is detected

*Note: This bit does not generate interrupt as it appears at the same time as the RXNE bit which itself generates an interrupting interrupt is generated on NF flag in case of Multi Buffer communication if the EIE bit is set.*

*Note: When the line is noise-free, the NF flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to [Section 30.3.5: USART receiver tolerance to clock deviation on page 991](#)).*

**Bit 1 FE:** Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by a software sequence (an read to the USART\_SR register followed by a read to the USART\_DR register).

0: No Framing error is detected

1: Framing error or break character is detected

*Note: This bit does not generate interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. If the word currently being transferred causes both frame error and overrun error, it is transferred and only the ORE bit is set.  
An interrupt is generated on FE flag in case of Multi Buffer communication if the EIE bit is set.*

**Bit 0 PE:** Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by a software sequence (a read from the status register followed by a read or write access to the USART\_DR data register). The software must wait for the RXNE flag to be set before clearing the PE bit.

An interrupt is generated if PEIE = 1 in the USART\_CR1 register.

0: No parity error

1: Parity error

### 30.6.2 Data register (USART\_DR)

Address offset: 0x04

Reset value: 0xFFFF XXXX

Bits 31:9 Reserved, must be kept at reset value

Bits 8:0 **DR[8:0]**: Data value

Contains the Received or Transmitted data character, depending on whether it is read from or written to.

The Data register performs a double function (read and write) since it is composed of two registers, one for transmission (TDR) and one for reception (RDR)

The TDR register provides the parallel interface between the internal bus and the output shift register (see [Figure 296: USART block diagram](#)).

The RDR register provides the parallel interface between the input shift register and the internal bus.

When transmitting with the parity enabled (PCE bit set to 1 in the USART\_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

### 30.6.3 Baud rate register (USART\_BRR)

*Note: The baud counters stop counting if the TE or RE bits are disabled respectively.*

Address offset: 0x08

Reset value: 0x0000 0000

|                    |    |    |    |    |    |    |    |    |    |    |    |                   |    |    |    |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|-------------------|----|----|----|
| 31                 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19                | 18 | 17 | 16 |
| Reserved           |    |    |    |    |    |    |    |    |    |    |    |                   |    |    |    |
| 15                 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3                 | 2  | 1  | 0  |
| DIV_Mantissa[11:0] |    |    |    |    |    |    |    |    |    |    |    | DIV_Fraction[3:0] |    |    |    |
| rw                 | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw                | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:4 **DIV\_Mantissa[11:0]**: mantissa of USARTDIV

These 12 bits define the mantissa of the USART Divider (USARTDIV)

Bits 3:0 **DIV\_Fraction[3:0]**: fraction of USARTDIV

These 4 bits define the fraction of the USART Divider (USARTDIV). When OVER8=1, the DIV\_Fraction3 bit is not considered and must be kept cleared.

### 30.6.4 Control register 1 (USART\_CR1)

Address offset: 0x0C

Reset value: 0x0000 0000

|          |          |    |    |      |     |    |      |       |      |        |        |    |    |     |     |
|----------|----------|----|----|------|-----|----|------|-------|------|--------|--------|----|----|-----|-----|
| 31       | 30       | 29 | 28 | 27   | 26  | 25 | 24   | 23    | 22   | 21     | 20     | 19 | 18 | 17  | 16  |
| Reserved |          |    |    |      |     |    |      |       |      |        |        |    |    |     |     |
| 15       | 14       | 13 | 12 | 11   | 10  | 9  | 8    | 7     | 6    | 5      | 4      | 3  | 2  | 1   | 0   |
| OVER8    | Reserved | UE | M  | WAKE | PCE | PS | PEIE | TXEIE | TCIE | RXNEIE | IDLEIE | TE | RE | RWU | SBK |
| rw       | Res.     | rw | rw | rw   | rw  | rw | rw   | rw    | rw   | rw     | rw     | rw | rw | rw  | rw  |

Bits 31:16 Reserved, must be kept at reset value

Bit 15 **OVER8**: Oversampling mode

0: oversampling by 16

1: oversampling by 8

*Note: Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes: when SCEN=1, IREN=1 or LINEN=1 then OVER8 is forced to '0 by hardware.*

Bit 14 Reserved, must be kept at reset value

Bit 13 **UE**: USART enable

When this bit is cleared, the USART prescalers and outputs are stopped and the end of the current byte transfer in order to reduce power consumption. This bit is set and cleared by software.

0: USART prescaler and outputs disabled

1: USART enabled

Bit 12 **M**: Word length

This bit determines the word length. It is set or cleared by software.

0: 1 Start bit, 8 Data bits, n Stop bit

1: 1 Start bit, 9 Data bits, n Stop bit

*Note: The M bit must not be modified during a data transfer (both transmission and reception)*

Bit 11 **WAKE**: Wake-up method

This bit determines the USART wake-up method, it is set or cleared by software.

0: Idle Line

1: Address Mark

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled

1: Parity control enabled

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.

0: Even parity

1: Odd parity

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever PE=1 in the USART\_SR register

Bit 7 **TXEIE**: TXE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever TXE=1 in the USART\_SR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever TC=1 in the USART\_SR register

Bit 5 **RXNEIE**: RXNE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever ORE=1 or RXNE=1 in the USART\_SR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited

1: An USART interrupt is generated whenever IDLE=1 in the USART\_SR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled

1: Transmitter is enabled

*Note: During transmission, a “0” pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word, except in smartcard mode.*

*When TE is set, there is a 1 bit-time delay before the transmission starts.*

Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled

1: Receiver is enabled and begins searching for a start bit

Bit 1 **RWU**: Receiver wake-up

This bit determines if the USART is in mute mode or not. It is set and cleared by software and can be cleared by hardware when a wake-up sequence is recognized.

0: Receiver in active mode

1: Receiver in mute mode

*Note: Before selecting Mute mode (by setting the RWU bit) the USART must first receive a data byte, otherwise it cannot function in Mute mode with wake-up by Idle line detection.*

*In Address Mark Detection wake-up configuration (WAKE bit=1) the RWU bit cannot be modified by software while the RXNE bit is set.*

Bit 0 **SBK**: Send break

This bit set is used to send break characters. It can be set and cleared by software. It should be set by software, and is reset by hardware during the stop bit of break.

0: No break character is transmitted.

1: Break character is transmitted.

### 30.6.5 Control register 2 (USART\_CR2)

Address offset: 0x10

Reset value: 0x0000 0000

| 31       | 30    | 29        | 28 | 27    | 26   | 25   | 24   | 23   | 22    | 21   | 20   | 19       | 18 | 17 | 16 |
|----------|-------|-----------|----|-------|------|------|------|------|-------|------|------|----------|----|----|----|
| Reserved |       |           |    |       |      |      |      |      |       |      |      |          |    |    |    |
| 15       | 14    | 13        | 12 | 11    | 10   | 9    | 8    | 7    | 6     | 5    | 4    | 3        | 2  | 1  | 0  |
| Res.     | LINEN | STOP[1:0] |    | CLKEN | CPOL | CPHA | LBCL | Res. | LBDIE | LBDL | Res. | ADD[3:0] |    |    |    |
|          | rw    | rw        | rw | rw    | rw   | rw   | rw   |      | rw    | rw   | rw   | rw       | rw | rw | rw |

Bits 31:15 Reserved, must be kept at reset value

Bit 14 **LINEN**: LIN mode enable

This bit is set and cleared by software.

0: LIN mode disabled

1: LIN mode enabled

The LIN mode enables the capability to send LIN Synch Breaks (13 low bits) using the SBK bit in the USART\_CR1 register, and to detect LIN Sync breaks.

Bits 13:12 **STOP**: STOP bits

These bits are used for programming the stop bits.

00: 1 Stop bit

01: 0.5 Stop bit

10: 2 Stop bits

11: 1.5 Stop bit

*Note: The 0.5 Stop bit and 1.5 Stop bit are not available for UART4 & UART5.*

Bit 11 **CLKEN**: Clock enable

This bit allows the user to enable the CK pin.

0: CK pin disabled

1: CK pin enabled

This bit is not available for UART4 & UART5.

Bit 10 **CPOL**: Clock polarity

This bit allows the user to select the polarity of the clock output on the CK pin in synchronous mode.

It works in conjunction with the CPHA bit to produce the desired clock/data relationship

0: Steady low value on CK pin outside transmission window.

1: Steady high value on CK pin outside transmission window.

This bit is not available for UART4 & UART5.

Bit 9 **CPHA**: Clock phase

This bit allows the user to select the phase of the clock output on the CK pin in synchronous mode.

It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see figures [308](#) to [309](#))

0: The first clock transition is the first data capture edge

1: The second clock transition is the first data capture edge

*Note: This bit is not available for UART4 & UART5.*

Bit 8 **LBCL**: Last bit clock pulse

This bit allows the user to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the CK pin

1: The clock pulse of the last data bit is output to the CK pin

*Note:* 1: The last bit is the 8th or 9th data bit transmitted depending on the 8 or 9 bit format selected by the M bit in the USART\_CR1 register.

2: This bit is not available for UART4 & UART5.

Bit 7 Reserved, must be kept at reset value

Bit 6 **LBDIE**: LIN break detection interrupt enable

Break interrupt mask (break detection using break delimiter).

0: Interrupt is inhibited

1: An interrupt is generated whenever LBD=1 in the USART\_SR register

Bit 5 **LBDL**: *lin* break detection length

This bit is for selection between 11 bit or 10 bit break detection.

0: 10-bit break detection

1: 11-bit break detection

Bit 4 Reserved, must be kept at reset value

Bits 3:0 **ADD[3:0]**: Address of the USART node

This bit-field gives the address of the USART node.

This is used in multiprocessor communication during mute mode, for wake up with address mark detection.

*Note:* These 3 bits (CPOL, CPHA, LBCL) should not be written while the transmitter is enabled.

### 30.6.6 Control register 3 (USART\_CR3)

Address offset: 0x14

Reset value: 0x0000 0000

|          |    |    |    |        |       |      |      |      |      |      |      |       |      |      |     |
|----------|----|----|----|--------|-------|------|------|------|------|------|------|-------|------|------|-----|
| 31       | 30 | 29 | 28 | 27     | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19    | 18   | 17   | 16  |
| Reserved |    |    |    |        |       |      |      |      |      |      |      |       |      |      |     |
| 15       | 14 | 13 | 12 | 11     | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3     | 2    | 1    | 0   |
| Reserved |    |    |    | ONEBIT | CTSIE | CTSE | RTSE | DMAT | DMAR | SCEN | NACK | HDSEL | IRLP | IREN | EIE |
|          |    |    |    | rw     | rw    | rw   | rw   | rw   | rw   | rw   | rw   | rw    | rw   | rw   | rw  |

Bits 31:12 Reserved, must be kept at reset value

Bit 11 **ONEBIT**: One sample bit method enable

This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NF) is disabled.

0: Three sample bit method

1: One sample bit method

*Note:* The ONEBIT feature applies only to data bits. It does not apply to START bit.

Bit 10 **CTSIE**: CTS interrupt enable

0: Interrupt is inhibited

1: An interrupt is generated whenever CTS=1 in the USART\_SR register

*Note:* This bit is not available for UART4 & UART5.

Bit 9 **CTSE**: CTS enable

0: CTS hardware flow control disabled

1: CTS mode enabled, data is only transmitted when the CTS input is asserted (tied to 0). If the CTS input is deasserted while a data is being transmitted, then the transmission is completed before stopping. If a data is written into the data register while CTS is deasserted, the transmission is postponed until CTS is asserted.

*Note: This bit is not available for UART4 & UART5.*

Bit 8 **RTSE**: RTS enable

0: RTS hardware flow control disabled

1: RTS interrupt enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is asserted (tied to 0) when a data can be received.

*Note: This bit is not available for UART4 & UART5.*

Bit 7 **DMAT**: DMA enable transmitter

This bit is set/reset by software

1: DMA mode is enabled for transmission.

0: DMA mode is disabled for transmission.

Bit 6 **DMAR**: DMA enable receiver

This bit is set/reset by software

1: DMA mode is enabled for reception

0: DMA mode is disabled for reception

Bit 5 **SCEN**: Smartcard mode enable

This bit is used for enabling Smartcard mode.

0: Smartcard Mode disabled

1: Smartcard Mode enabled

*Note: This bit is not available for UART4 & UART5.*

Bit 4 **NACK**: Smartcard NACK enable

0: NACK transmission in case of parity error is disabled

1: NACK transmission during parity error is enabled

*Note: This bit is not available for UART4 & UART5.*

Bit 3 **HDSEL**: Half-duplex selection

Selection of Single-wire Half-duplex mode

0: Half duplex mode is not selected

1: Half duplex mode is selected

Bit 2 **IRLP**: IrDA low-power

This bit is used for selecting between normal and low-power IrDA modes

0: Normal mode

1: Low-power mode

Bit 1 **IREN**: IrDA mode enable

This bit is set and cleared by software.

0: IrDA disabled

1: IrDA enabled

Bit 0 **EIE**: Error interrupt enable

Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the USART\_SR register) in case of Multi Buffer Communication (DMAR=1 in the USART\_CR3 register).

0: Interrupt is inhibited

1: An interrupt is generated whenever DMAR=1 in the USART\_CR3 register and FE=1 or ORE=1 or NF=1 in the USART\_SR register.

### 30.6.7 Guard time and prescaler register (USART\_GTPR)

Address offset: 0x18

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| GT[7:0]  |    |    |    |    |    |    |    | PSC[7:0] |    |    |    |    |    |    |    |
| rw       | rw | rw | rw | rw | rw | rw | rw | rw       | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:8 **GT[7:0]**: Guard time value

This bit-field gives the Guard time value in terms of number of baud clocks.

This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.

*Note: This bit is not available for UART4 & UART5.*

Bits 7:0 **PSC[7:0]**: Prescaler value

– In IrDA Low-power mode:

**PSC[7:0]** = IrDA Low-Power Baud Rate

Used for programming the prescaler for dividing the system clock to achieve the low-power frequency:

The source clock is divided by the value given in the register (8 significant bits):

00000000: Reserved - do not program this value

00000001: divides the source clock by 1

00000010: divides the source clock by 2

...

– In normal IrDA mode: PSC must be set to 00000001.

– In smartcard mode:

**PSC[4:0]**: Prescaler value

Used for programming the prescaler for dividing the system clock to provide the smartcard clock.

The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:

00000: Reserved - do not program this value

00001: divides the source clock by 2

00010: divides the source clock by 4

00011: divides the source clock by 6

...

*Note: 1: Bits [7:5] have no effect if Smartcard mode is used.*

*2: This bit is not available for UART4 & UART5.*

### 30.6.8 USART register map

The table below gives the USART register map and reset values.

**Table 150. USART register map and reset values**

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21                 | 20         | 19    | 18   | 17   | 16   | 15       | 14       | 13    | 12       | 11                 | 10     | 9       | 8   | 7   | 6   | 5    | 4    | 3   | 2  | 1  | 0  |
|--------|-------------|----------|----|----|----|----|----|----|----|----|----|--------------------|------------|-------|------|------|------|----------|----------|-------|----------|--------------------|--------|---------|-----|-----|-----|------|------|-----|----|----|----|
| 0x00   | USART_SR    | Reserved |    |    |    |    |    |    |    |    |    |                    |            |       |      |      |      |          |          |       |          |                    |        | CTS     | LBD | TXE | TC  | RXNE | IDLE | ORE | NF | FE | PE |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |                    |            |       |      |      |      |          |          |       |          |                    |        | 0       | 0   | 1   | 1   | 0    | 0    | 0   | 0  | 0  |    |
| 0x04   | USART_DR    | Reserved |    |    |    |    |    |    |    |    |    |                    |            |       |      |      |      |          |          |       |          |                    |        | DR[8:0] |     |     |     |      |      |     |    |    |    |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |                    |            |       |      |      |      |          |          |       |          |                    |        | 0       | 0   | 0   | 0   | 0    | 0    | 0   | 0  | 0  |    |
| 0x08   | USART_BRR   | Reserved |    |    |    |    |    |    |    |    |    | DIV_Mantissa[15:4] |            |       |      |      |      |          |          |       |          | DIV_Fraction [3:0] |        |         |     |     |     |      |      |     |    |    |    |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 31 Secure digital input/output interface (SDIO)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 31.1 SDIO main features

The SD/SDIO MMC card host interface (SDIO) provides an interface between the APB2 peripheral bus and MultiMediaCards (MMCs), SD memory cards, SDIO cards and CE-ATA devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at <http://www.jedec.org/>, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at <http://www.sdcard.org>.

CE-ATA system specifications are available through the CE-ATA workgroup website.

The SDIO features include the following:

- Full compliance with *MultiMediaCard System Specification Version 4.2*. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit
- Full compatibility with previous versions of MultiMediaCards (forward compatibility)
- Full compliance with *SD Memory Card Specifications Version 2.0*
- Full compliance with *SD I/O Card Specification Version 2.0*: card support for two different databus modes: 1-bit (default) and 4-bit
- Full support of the CE-ATA features (full compliance with *CE-ATA digital protocol Rev1.1*)
- Data transfer up to 50 MHz for the 8 bit mode
- Data and command output enable signals to control external bidirectional drivers.

*Note:* The SDIO does not have an SPI-compatible communication mode.

*The SD memory card protocol is a superset of the MultiMediaCard protocol as defined in the MultiMediaCard system specification V2.11. Several commands required for SD memory devices are not supported by either SD I/O-only cards or the I/O portion of combo cards. Some of these commands have no use in SD I/O devices, such as erase commands, and thus are not supported in the SDIO. In addition, several commands are different between SD memory cards and SD I/O cards and thus are not supported in the SDIO. For details refer to SD I/O card Specification Version 1.0. CE-ATA is supported over the MMC electrical interface using a protocol that utilizes the existing MMC access primitives. The interface electrical and signaling definition is as defined in the MMC reference.*

The MultiMediaCard/SD bus connects cards to the controller.

The current version of the SDIO supports only one SD/SDIO/MMC4.2 card at any one time and a stack of MMC4.1 or previous.

## 31.2 SDIO bus topology

Communication over the bus is based on command and data transfers.

The basic transaction on the MultiMediaCard/SD/SD I/O bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers to/from SD/SDIO memory cards are done in data blocks. Data transfers to/from MMC are done data blocks or streams. Data transfers to/from the CE-ATA Devices are done in data blocks.

**Figure 321. SDIO “no response” and “no data” operations**

**Figure 322. SDIO (multiple) block read operation**

Figure 323. SDIO (multiple) block write operation

*Note:* The SDIO does not send any data as long as the Busy signal is asserted (SDIO\_D0 pulled low).

Figure 324. SDIO sequential read operation

Figure 325. SDIO sequential write operation

### 31.3 SDIO functional description

The SDIO consists of two parts:

- The SDIO adapter block provides all functions specific to the MMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The APB2 interface accesses the SDIO adapter registers, and generates interrupt and DMA request signals.

Figure 326. SDIO block diagram

By default SDIO\_D0 is used for data transfer. After initialization, the host can change the databus width.

If a MultiMediaCard is connected to the bus, SDIO\_D0, SDIO\_D[3:0] or SDIO\_D[7:0] can be used for data transfer. MMC V3.31 or previous, supports only 1 bit of data so only SDIO\_D0 can be used.

If an SD or SD I/O card is connected to the bus, data transfer can be configured by the host to use SDIO\_D0 or SDIO\_D[3:0]. All data lines are operating in push-pull mode.

**SDIO\_CMD** has two operational modes:

- Open-drain for initialization (only for MMCV3.31 or previous)
- Push-pull for command transfer (SD/SD I/O card MMC4.2 use push-pull drivers also for initialization)

**SDIO\_CK** is the clock to the card: one bit is transferred on both command and data lines with each clock cycle.

The SDIO uses two clock signals:

- SDIO adapter clock SDIOCLK up to 50 MHz (48 MHz when in use with USB)
- APB2 bus clock (PCLK2)

PCLK2 and SDIO\_CK clock frequencies must respect the following condition:

$$\text{Frequency(PCLK2)} \geq 3 / 8 \times \text{Frequency(SDIO\_CK)}$$

The signals shown in [Table 151](#) are used on the MultiMediaCard/SD/SD I/O card bus.

Table 151. SDIO I/O definitions

| Pin         | Direction     | Description                                                                                 |
|-------------|---------------|---------------------------------------------------------------------------------------------|
| SDIO_CK     | Output        | MultiMediaCard/SD/SDIO card clock. This pin is the clock from host to card.                 |
| SDIO_CMD    | Bidirectional | MultiMediaCard/SD/SDIO card command. This pin is the bidirectional command/response signal. |
| SDIO_D[7:0] | Bidirectional | MultiMediaCard/SD/SDIO card data. These pins are the bidirectional databus.                 |

### 31.3.1 SDIO adapter

Figure 327 shows a simplified block diagram of an SDIO adapter.

Figure 327. SDIO adapter

The SDIO adapter is a multimedia/secure digital memory card bus master that provides an interface to a multimedia card stack or to a secure digital memory card. It consists of five subunits:

- Adapter register block
- Control unit
- Command path
- Data path
- Data FIFO

**Note:** The adapter registers and FIFO use the APB2 bus clock domain (PCLK2). The control unit, command path and data path use the SDIO adapter clock domain (SDIOCLK).

#### Adapter register block

The adapter register block contains all system registers. This block also generates the signals that clear the static flags in the multimedia card. The clear signals are generated when 1 is written into the corresponding bit location in the SDIO Clear register.

### Control unit

The control unit contains the power management functions and the clock divider for the memory card clock.

There are three power phases:

- power-off
- power-up
- power-on

**Figure 328. Control unit**

The control unit is illustrated in [Figure 328](#). It consists of a power management subunit and a clock management subunit.

The power management subunit disables the card bus output signals during the power-off and power-up phases.

The clock management subunit generates and controls the SDIO\_CLK signal. The SDIO\_CLK output can use either the clock divide or the clock bypass mode. The clock output is inactive:

- after reset
- during the power-off or power-up phases
- if the power saving mode is enabled and the card bus is in the Idle state (eight clock periods after both the command and data path subunits enter the Idle phase)

## Command path

The command path unit sends commands to and receives responses from the cards.

**Figure 329. SDIO adapter command path**

- Command path state machine (CPSM)
  - When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent, the command path state machine (CPSM) sets the status flags and enters the Idle state if a response is not required. If a response is required, it waits for the response (see [Figure 330 on page 1029](#)). When the response is received, the received CRC code and the internally generated code are compared, and the appropriate status flags are set.

Figure 330. Command path state machine (CPSM)

When the Wait state is entered, the command timer starts running. If the timeout is reached before the CPSM moves to the Receive state, the timeout flag is set and the Idle state is entered.

**Note:** The command timeout has a fixed value of 64 SDIO\_CLK clock periods.

If the interrupt bit is set in the command register, the timer is disabled and the CPSM waits for an interrupt request from one of the cards. If a pending bit is set in the command register, the CPSM enters the Pend state, and waits for a CmdPend signal from the data path subunit. When CmdPend is detected, the CPSM moves to the Send state. This enables the data counter to trigger the stop command transmission.

**Note:** The CPSM remains in the Idle state for at least eight SDIO\_CLK periods to meet the  $N_{CC}$  and  $N_{RC}$  timing constraints.  $N_{CC}$  is the minimum delay between two host commands, and  $N_{RC}$  is the minimum delay between the host command and the card response.

Figure 331. SDIO command transfer

- Command format

- Command: a command is a token that starts an operation. Commands are sent from the host either to a single card (addressed command) or to all connected cards (broadcast command are available for MMC V3.31 or previous). Commands are transferred serially on the CMD line. All commands have a fixed length of 48 bits. The general format for a command token for MultiMediaCards, SD-Memory cards and SDIO-Cards is shown in [Table 152](#). CE-ATA commands are an extension of MMC commands V4.2, and so have the same format.

The command path operates in a half-duplex mode, so that commands and responses can either be sent or received. If the CPSM is not in the Send state, the SDIO\_CMD output is in the Hi-Z state, as shown in [Figure 331 on page 1030](#). Data on SDIO\_CMD are synchronous with the rising edge of SDIO\_CK. [Table 152](#) shows the command format.

Table 152. Command format

| Bit position | Width | Value | Description      |
|--------------|-------|-------|------------------|
| 47           | 1     | 0     | Start bit        |
| 46           | 1     | 1     | Transmission bit |
| [45:40]      | 6     | -     | Command index    |
| [39:8]       | 32    | -     | Argument         |
| [7:1]        | 7     | -     | CRC7             |
| 0            | 1     | 1     | End bit          |

- Response: a response is a token that is sent from an addressed card (or synchronously from all connected cards for MMC V3.31 or previous), to the host as an answer to a previously received command. Responses are transferred serially on the CMD line.

The SDIO supports two response types. Both use CRC error checking:

- 48 bit short response
- 136 bit long response

**Note:** *If the response does not contain a CRC (CMD1 response), the device driver must ignore the CRC failed status.*

Table 153. Short response format

| Bit position | Width | Value | Description      |
|--------------|-------|-------|------------------|
| 47           | 1     | 0     | Start bit        |
| 46           | 1     | 0     | Transmission bit |
| [45:40]      | 6     | -     | Command index    |
| [39:8]       | 32    | -     | Argument         |
| [7:1]        | 7     | -     | CRC7(or 1111111) |
| 0            | 1     | 1     | End bit          |

Table 154. Long response format

| Bit position | Width | Value  | Description                          |
|--------------|-------|--------|--------------------------------------|
| 135          | 1     | 0      | Start bit                            |
| 134          | 1     | 0      | Transmission bit                     |
| [133:128]    | 6     | 111111 | Reserved                             |
| [127:1]      | 127   | -      | CID or CSD (including internal CRC7) |
| 0            | 1     | 1      | End bit                              |

The command register contains the command index (six bits sent to a card) and the command type. These determine whether the command requires a response, and whether the response is 48 or 136 bits long (see [Section 31.9.4 on page 1065](#)). The command path implements the status flags shown in [Table 155](#):

Table 155. Command path status flags

| Flag     | Description                                               |
|----------|-----------------------------------------------------------|
| CMDREND  | Set if response CRC is OK.                                |
| CCRCFAIL | Set if response CRC fails.                                |
| CMDSENT  | Set when command (that does not require response) is sent |
| CTIMEOUT | Response timeout.                                         |
| CMDACT   | Command transfer in progress.                             |

The CRC generator calculates the CRC checksum for all bits before the CRC code. This includes the start bit, transmitter bit, command index, and command argument (or card status). The CRC checksum is calculated for the first 120 bits of CID or CSD for the long response format. Note that the start bit, transmitter bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:

$$\text{CRC}[6:0] = \text{Remainder} [(M(x) * x^7) / G(x)]$$

$$G(x) = x^7 + x^3 + 1$$

$$M(x) = (\text{start bit}) * x^{39} + \dots + (\text{last bit before CRC}) * x^0, \text{ or}$$

$$M(x) = (\text{start bit}) * x^{119} + \dots + (\text{last bit before CRC}) * x^0$$

## Data path

The data path subunit transfers data to and from cards. [Figure 332](#) shows a block diagram of the data path.

**Figure 332. Data path**

The card databus width can be programmed using the clock control register. If the 4-bit wide bus mode is enabled, data is transferred at four bits per clock cycle over all four data signals (SDIO\_D[3:0]). If the 8-bit wide bus mode is enabled, data is transferred at eight bits per clock cycle over all eight data signals (SDIO\_D[7:0]). If the wide bus mode is not enabled, only one bit per clock cycle is transferred over SDIO\_D0.

Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait\_S or Wait\_R state when it is enabled:

- Send: the DPSM moves to the Wait\_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait\_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.

### Data path state machine (DPSM)

The DPSM operates at SDIO\_CK frequency. Data on the card bus signals is synchronous to the rising edge of SDIO\_CK. The DPSM has six states, as shown in [Figure 333: Data path state machine \(DPSM\)](#).

Figure 333. Data path state machine (DPSM)

- Idle: the data path is inactive, and the SDIO\_D[7:0] outputs are in Hi-Z. When the data control register is written and the enable bit is set, the DPSM loads the data counter with a new value and, depending on the data direction bit, moves to either the Wait\_S or the Wait\_R state.
- Wait\_R: if the data counter equals zero, the DPSM moves to the Idle state when the receive FIFO is empty. If the data counter is not zero, the DPSM waits for a start bit on SDIO\_D. The DPSM moves to the Receive state if it receives a start bit before a timeout, and loads the data block counter. If it reaches a timeout before it detects a start bit, or a start bit error occurs, it moves to the Idle state and sets the timeout status flag.
- Receive: serial data received from a card is packed in bytes and written to the data FIFO. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block or stream:
  - In block mode, when the data block counter reaches zero, the DPSM waits until it receives the CRC code. If the received code matches the internally generated

CRC code, the DPSM moves to the Wait\_R state. If not, the CRC fail status flag is set and the DPSM moves to the Idle state.

- In stream mode, the DPSM receives data while the data counter is not zero. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait\_R state.

If a FIFO overrun error occurs, the DPSM sets the FIFO error flag and moves to the Idle state:

- Wait\_S: the DPSM moves to the Idle state if the data counter is zero. If not, it waits until the data FIFO empty flag is deasserted, and moves to the Send state.

*Note:* The DPSM remains in the Wait\_S state for at least two clock periods to meet the  $N_{WR}$  timing requirements, where  $N_{WR}$  is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- Send: the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block or stream:
  - In block mode, when the data block counter reaches zero, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state.
  - In stream mode, the DPSM sends data to a card while the enable bit is high and the data counter is not zero. It then moves to the Idle state.

If a FIFO underrun error occurs, the DPSM sets the FIFO error flag and moves to the Idle state.

- Busy: the DPSM waits for the CRC status flag:
  - If it does not receive a positive CRC status, it moves to the Idle state and sets the CRC fail status flag.
  - If it receives a positive CRC status, it moves to the Wait\_S state if SDIO\_D0 is not low (the card is not busy).

If a timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag and moves to the Idle state.

The data timer is enabled when the DPSM is in the Wait\_R or Busy state, and generates the data timeout error:

- When transmitting data, the timeout occurs if the DPSM stays in the Busy state for longer than the programmed timeout period
- When receiving data, the timeout occurs if the end of the data is not true, and if the DPSM stays in the Wait\_R state for longer than the programmed timeout period.
- **Data:** data can be transferred from the card to the host or vice versa. Data is transferred via the data lines. They are stored in a FIFO of 32 words, each word is 32 bits wide.

**Table 156. Data token format**

| Description | Start bit | Data | CRC16 | End bit |
|-------------|-----------|------|-------|---------|
| Block Data  | 0         | -    | yes   | 1       |
| Stream Data | 0         | -    | no    | 1       |

## Data FIFO

The data FIFO (first-in-first-out) subunit is a data buffer with a transmit and receive unit.

The FIFO contains a 32-bit wide, 32-word deep data buffer, and transmit and receive logic. Because the data FIFO operates in the APB2 clock domain (PCLK2), all signals from the subunits in the SDIO clock domain (SDIOCLK) are resynchronized.

Depending on the TXACT and RXACT flags, the FIFO can be disabled, transmit enabled, or receive enabled. TXACT and RXACT are driven by the data path subunit and are mutually exclusive:

- The transmit FIFO refers to the transmit logic and data buffer when TXACT is asserted
- The receive FIFO refers to the receive logic and data buffer when RXACT is asserted
- **Transmit FIFO:**  
Data can be written to the transmit FIFO through the APB2 interface when the SDIO is enabled for transmission.  
The transmit FIFO is accessible via 32 sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out.  
If the transmit FIFO is disabled, all status flags are deasserted. The data path subunit asserts TXACT when it transmits data.

**Table 157. Transmit FIFO status flags**

| Flag     | Description                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------|
| TXFIFO   | Set to high when all 32 transmit FIFO words contain valid data.                                        |
| TXFIFOE  | Set to high when the transmit FIFO does not contain valid data.                                        |
| TXFIFOHE | Set to high when 8 or more transmit FIFO words are empty. This flag can be used as a DMA request.      |
| TXDAVL   | Set to high when the transmit FIFO contains valid data. This flag is the inverse of the TXFIFOE flag.  |
| TXUNDERR | Set to high when an underrun error occurs. This flag is cleared by writing to the SDIO Clear register. |

- **Receive FIFO**  
When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. If the receive FIFO is disabled, all status flags are deasserted, and the read and write pointers are reset. The data path subunit asserts RXACT when it receives data. [Table 158](#) lists the receive FIFO status flags. The receive FIFO is accessible via 32 sequential addresses.

Table 158. Receive FIFO status flags

| Flag     | Description                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------|
| RXFIFO   | Set to high when all 32 receive FIFO words contain valid data                                             |
| RXFIFOE  | Set to high when the receive FIFO does not contain valid data.                                            |
| RXFIFOHF | Set to high when 8 or more receive FIFO words contain valid data. This flag can be used as a DMA request. |
| RXDAVL   | Set to high when the receive FIFO is not empty. This flag is the inverse of the RXFIFOE flag.             |
| RXOVERR  | Set to high when an overrun error occurs. This flag is cleared by writing to the SDIO Clear register.     |

### 31.3.2 SDIO APB2 interface

The APB2 interface generates the interrupt and DMA requests, and accesses the SDIO adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt/DMA logic.

#### SDIO interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the selected status flags is high. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set.

#### SDIO/DMA interface - procedure for data transfers between the SDIO and memory

In the example shown, the transfer is from the SDIO host controller to an MMC (512 bytes using CMD24 (WRITE\_BLOCK)). The SDIO FIFO is filled by data stored in a memory using the DMA controller.

1. Do the card identification process
2. Increase the SDIO\_CK frequency
3. Select the card by sending CMD7
4. Configure the DMA2 as follows:
  - a) Enable DMA2 controller and clear any pending interrupts.
  - b) Program the DMA2\_Stream3 or DMA2\_Stream6 Channel4 source address register with the memory location's base address and DMA2\_Stream3 or

- DMA2\_Stream6 Channel4 destination address register with the SDIO\_FIFO register address.
- c) Program DMA2\_Stream3 or DMA2\_Stream6 Channel4 control register (memory increment, not peripheral increment, peripheral and source width is word size).
  - d) Program DMA2\_Stream3 or DMA2\_Stream6 Channel4 to select the peripheral as flow controller (set PFCTRL bit in DMA\_S3CR or DMA\_S6CR configuration register).
  - e) Configure the incremental burst transfer to 4 beats (at least from peripheral side) in DMA2\_Stream3 or DMA2\_Stream6 Channel4.
  - f) Enable DMA2\_Stream3 or DMA2\_Stream6 Channel4
5. Send CMD24 (WRITE\_BLOCK) as follows:
- a) Program the SDIO data length register (SDIO data timer register should be already programmed before the card identification process).
  - b) Program the SDIO argument register with the address location of the card where data is to be transferred.
  - c) Program the SDIO command register: CmdIndex with 24 (WRITE\_BLOCK); WaitResp with '1' (SDIO card host waits for a response); CPSMEN with '1' (SDIO card host enabled to send a command). Other fields are at their reset value.
  - d) Wait for SDIO\_STA[6] = CMDREND interrupt, then program the SDIO data control register: DTEN with '1' (SDIO card host enabled to send data); DTDIR with '0' (from controller to card); DTMODE with '0' (block data transfer); DMAEN with '1' (DMA enabled); DBLOCKSIZE with 0x9 (512 bytes). Other fields are don't care.
  - e) Wait for SDIO\_STA[10] = DBCKEND.
6. Check that no channels are still enabled by polling the DMA Enabled Channel Status register.

## 31.4 Card functional description

### 31.4.1 Card identification mode

While in card identification mode the host resets all cards, validates the operation voltage range, identifies cards and sets a relative card address (RCA) for each card on the bus. All data communications in the card identification mode use the command line (CMD) only.

### 31.4.2 Card reset

The `GO_IDLE_STATE` command (CMD0) is the software reset command and it puts the MultiMediaCard and SD memory in the Idle state. The `IO_RW_DIRECT` command (CMD52) resets the SD I/O card. After power-up or CMD0, all cards output bus drivers are in the high-impedance state and the cards are initialized with a default relative card address (RCA=0x0001) and with a default driver stage register setting (lowest speed, highest driving current capability).

### 31.4.3 Operating voltage range validation

All cards can communicate with the SDIO card host using any operating voltage within the specification range. The supported minimum and maximum  $V_{DD}$  values are defined in the operation conditions register (OCR) on the card.

Cards that store the card identification number (CID) and card specific data (CSD) in the payload memory are able to communicate this information only under data-transfer  $V_{DD}$  conditions. When the SDIO card host module and the card have incompatible  $V_{DD}$  ranges, the card is not able to complete the identification cycle and cannot send CSD data. For this purpose, the special commands, `SEND_OP_COND` (CMD1), `SD_APP_OP_COND` (ACMD41 for SD Memory), and `IO_SEND_OP_COND` (CMD5 for SD I/O), are designed to provide a mechanism to identify and reject cards that do not match the  $V_{DD}$  range desired by the SDIO card host. The SDIO card host sends the required  $V_{DD}$  voltage window as the operand of these commands. Cards that cannot perform data transfer in the specified range disconnect from the bus and go to the inactive state.

By using these commands without including the voltage range as the operand, the SDIO card host can query each card and determine the common voltage range before placing out-of-range cards in the inactive state. This query is used when the SDIO card host is able to select a common voltage range or when the user requires notification that cards are not usable.

#### 31.4.4 Card identification process

The card identification process differs for MultiMediaCards and SD cards. For MultiMediaCard cards, the identification process starts at clock rate  $F_{od}$ . The SDIO\_CMD line output drivers are open-drain and allow parallel card operation during this process. The registration process is accomplished as follows:

1. The bus is activated.
2. The SDIO card host broadcasts `SEND_OP_COND` (CMD1) to receive operation conditions.
3. The response is the wired AND operation of the operation condition registers from all cards.
4. Incompatible cards are placed in the inactive state.
5. The SDIO card host broadcasts `ALL_SEND_CID` (CMD2) to all active cards.
6. The active cards simultaneously send their CID numbers serially. Cards with outgoing CID bits that do not match the bits on the command line stop transmitting and must wait for the next identification cycle. One card successfully transmits a full CID to the SDIO card host and enters the Identification state.
7. The SDIO card host issues `SET_RELATIVE_ADDR` (CMD3) to that card. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state, it does not react to further identification cycles, and its output switches from open-drain to push-pull.
8. The SDIO card host repeats steps 5 through 7 until it receives a timeout condition.

For the SD card, the identification process starts at clock rate  $F_{od}$ , and the SDIO\_CMD line output drives are push-pull drivers instead of open-drain. The registration process is accomplished as follows:

1. The bus is activated.
2. The SDIO card host broadcasts `SD_APP_OP_COND` (ACMD41).
3. The cards respond with the contents of their operation condition registers.
4. The incompatible cards are placed in the inactive state.
5. The SDIO card host broadcasts `ALL_SEND_CID` (CMD2) to all active cards.
6. The cards send back their unique card identification numbers (CIDs) and enter the Identification state.
7. The SDIO card host issues `SET_RELATIVE_ADDR` (CMD3) to an active card with an address. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state. The SDIO card host can reissue this command to change the RCA. The RCA of the card is the last assigned value.
8. The SDIO card host repeats steps 5 through 7 with all active cards.

For the SD I/O card, the registration process is accomplished as follows:

1. The bus is activated.
2. The SDIO card host sends `IO_SEND_OP_COND` (CMD5).
3. The cards respond with the contents of their operation condition registers.
4. The incompatible cards are set to the inactive state.
5. The SDIO card host issues `SET_RELATIVE_ADDR` (CMD3) to an active card with an address. This new address is called the relative card address (RCA); it is shorter than the CID and addresses the card. The assigned card changes to the Standby state. The SDIO card host can reissue this command to change the RCA. The RCA of the card is the last assigned value.

### 31.4.5 Block write

During block write (CMD24 - 27) one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. A card supporting block write is always able to accept a block of data defined by `WRITE_BL_LEN`. If the CRC fails, the card indicates the failure on the `SDIO_D` line and the transferred data are discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and, block misalignment is not allowed (CSD parameter `WRITE_BLK_MISALIGN` is not set), the card detects the block misalignment error before the beginning of the first misaligned block. (`ADDRESS_ERROR` error bit is set in the status register). The write operation is also aborted if the host tries to write over a write-protected area. In this case, however, the card sets the `WP_VIOLATION` bit.

Programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents. Some cards may require long and unpredictable times to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the `SDIO_D` line low if its write buffer is full and unable to accept new data from a new `WRITE_BLOCK` command. The host may poll the status of the card with a `SEND_STATUS` command (CMD13) at any time, and the card responds with its status. The `READY_FOR_DATA` status bit indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing CMD7 (to

select a different card), which places the card in the Disconnect state and release the SDIO\_D line(s) without interrupting the write operation. When selecting the card again, it reactivates busy indication by pulling SDIO\_D to low if programming is still in progress and the write buffer is unavailable.

### 31.4.6 Block read

In Block read mode the basic unit of data transfer is a block whose maximum size is defined in the CSD (READ\_BL\_LEN). If READ\_BL\_PARTIAL is set, smaller blocks whose start and end addresses are entirely contained within one physical block (as defined by READ\_BL\_LEN) may also be transmitted. A CRC is appended to the end of each block, ensuring data transfer integrity. CMD17 (READ\_SINGLE\_BLOCK) initiates a block read and after completing the transfer, the card returns to the Transfer state.

CMD18 (READ\_MULTIPLE\_BLOCK) starts a transfer of several consecutive blocks.

The host can abort reading at any time, within a multiple block operation, regardless of its type. Transaction abort is done by sending the stop transmission command.

If the card detects an error (for example, out of range, address misalignment or internal error) during a multiple block read operation (both types) it stops the data transmission and remains in the data state. The host must then abort the operation by sending the stop transmission command. The read error is reported in the response to the stop transmission command.

If the host sends a stop transmission command after the card transmits the last block of a multiple block operation with a predefined number of blocks, it is responded to as an illegal command, since the card is no longer in the data state. If the host uses partial blocks whose accumulated length is not block-aligned and block misalignment is not allowed, the card detects a block misalignment error condition at the beginning of the first misaligned block (ADDRESS\_ERROR error bit is set in the status register).

### 31.4.7 Stream access, stream write and stream read (MultiMediaCard only)

In stream mode, data is transferred in bytes and no CRC is appended at the end of each block.

#### Stream write (MultiMediaCard only)

WRITE\_DAT\_UNTIL\_STOP (CMD20) starts the data transfer from the SDIO card host to the card, beginning at the specified address and continuing until the SDIO card host issues a stop command. When partial blocks are allowed (CSD parameter WRITE\_BL\_PARTIAL is set), the data stream can start and stop at any address within the card address space, otherwise it can only start and stop at block boundaries. Because the amount of data to be transferred is not determined in advance, a CRC cannot be used. When the end of the memory range is reached while sending data and no stop command is sent by the SD card host, any additional transferred data are discarded.

The maximum clock frequency for a stream write operation is given by the following equation fields of the card-specific data register:

$$\text{Maximumspeed} = \text{MIN}(\text{TRANSPEED}, \frac{(8 \times 2^{\text{writeblen}})(-\text{NSAC})}{\text{TAAC} \times \text{R2WFACTOR}})$$

- Maximumspeed = maximum write frequency
- TRANSPEED = maximum data transfer rate
- writeblen = maximum write data block length
- NSAC = data read access time 2 in CLK cycles
- TAAC = data read access time 1
- R2WFACTOR = write speed factor

If the host attempts to use a higher frequency, the card may not be able to process the data and stop programming, set the **OVERRUN** error bit in the status register, and while ignoring all further data transfer, wait (in the receive data state) for a stop command. The write operation is also aborted if the host tries to write over a write-protected area. In this case, however, the card sets the **WP\_VIOLATION** bit.

### Stream read (MultiMediaCard only)

**READ\_DAT\_UNTIL\_STOP** (CMD11) controls a stream-oriented data transfer.

This command instructs the card to send its data, starting at a specified address, until the SDIO card host sends **STOP\_TRANSMISSION** (CMD12). The stop command has an execution delay due to the serial command transmission and the data transfer stops after the end bit of the stop command. When the end of the memory range is reached while sending data and no stop command is sent by the SDIO card host, any subsequent data sent are considered undefined.

The maximum clock frequency for a stream read operation is given by the following equation and uses fields of the card specific data register.

$$\text{Maximumspeed} = \text{MIN}(\text{TRANSPEED}, \frac{(8 \times 2^{\text{readblen}})(-\text{NSAC})}{\text{TAAC} \times \text{R2WFACTOR}})$$

- Maximumspeed = maximum read frequency
- TRANSPEED = maximum data transfer rate
- readblen = maximum read data block length
- writeblen = maximum write data block length
- NSAC = data read access time 2 in CLK cycles
- TAAC = data read access time 1
- R2WFACTOR = write speed factor

If the host attempts to use a higher frequency, the card is not able to sustain data transfer. If this happens, the card sets the **UNDERRUN** error bit in the status register, aborts the transmission and waits in the data state for a stop command.

### 31.4.8 Erase: group erase and sector erase

The erasable unit of the MultiMediaCard is the erase group. The erase group is measured in write blocks, which are the basic writable units of the card. The size of the erase group is a card-specific parameter and defined in the CSD.

The host can erase a contiguous range of Erase Groups. Starting the erase process is a three-step sequence.

First the host defines the start address of the range using the `ERASE_GROUP_START` (CMD35) command, next it defines the last address of the range using the `ERASE_GROUP_END` (CMD36) command and, finally, it starts the erase process by issuing the `ERASE` (CMD38) command. The address field in the erase commands is an Erase Group address in byte units. The card ignores all LSBs below the Erase Group size, effectively rounding the address down to the Erase Group boundary.

If an erase command is received out of sequence, the card sets the `ERASE_SEQ_ERROR` bit in the status register and resets the whole sequence.

If an out-of-sequence (neither of the erase commands, except `SEND_STATUS`) command received, the card sets the `ERASE_RESET` status bit in the status register, resets the erase sequence and executes the last command.

If the erase range includes write protected blocks, they are left intact and only unprotected blocks are erased. The `WP_ERASE_SKIP` status bit in the status register is set.

The card indicates that an erase is in progress by holding `SDIO_D` low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

### 31.4.9 Wide bus selection or deselection

Wide bus (4-bit bus width) operation mode is selected or deselected using `SET_BUS_WIDTH` (ACMD6). The default bus width after power-up or `GO_IDLE_STATE` (CMD0) is 1 bit. `SET_BUS_WIDTH` (ACMD6) is only valid in a transfer state, which means that the bus width can be changed only after a card is selected by `SELECT/DESELECT_CARD` (CMD7).

### 31.4.10 Protection management

Three write protection methods for the cards are supported in the SDIO card host module:

1. internal card write protection (card responsibility)
2. mechanical write protection switch (SDIO card host module responsibility only)
3. password-protected card lock operation

#### Internal card write protection

Card data can be protected against write and erase. By setting the permanent or temporary write-protect bits in the CSD, the entire card can be permanently write-protected by the manufacturer or content provider. For cards that support write protection of groups of sectors by setting the `WP_GRP_ENABLE` bit in the CSD, portions of the data can be protected, and the write protection can be changed by the application. The write protection is in units of `WP_GRP_SIZE` sectors as specified in the CSD. The `SET_WRITE_PROT` and `CLR_WRITE_PROT` commands control the protection of the addressed group. The `SEND_WRITE_PROT` command is similar to a single block read command. The card sends a data block containing 32 write protection bits (representing 32 write protect groups starting

at the specified address) followed by 16 CRC bits. The address field in the write protect commands is a group address in byte units.

The card ignores all LSBs below the group size.

### Mechanical write protect switch

A mechanical sliding tab on the side of the card allows the user to set or clear the write protection on a card. When the sliding tab is positioned with the window open, the card is write-protected, and when the window is closed, the card contents can be changed. A matched switch on the socket side indicates to the SDIO card host module that the card is write-protected. The SDIO card host module is responsible for protecting the card. The position of the write protect switch is unknown to the internal circuitry of the card.

### Password protect

The password protection feature enables the SDIO card host module to lock and unlock a card with a password. The password is stored in the 128-bit PWD register and its size is set in the 8-bit PWD\_LEN register. These registers are nonvolatile so that a power cycle does not erase them. Locked cards respond to and execute certain commands. This means that the SDIO card host module is allowed to reset, initialize, select, and query for status, however it is not allowed to access data on the card. When the password is set (as indicated by a nonzero value of PWD\_LEN), the card is locked automatically after power-up. As with the CSD and CID register write commands, the lock/unlock commands are available in the transfer state only. In this state, the command does not include an address argument and the card must be selected before using it. The card lock/unlock commands have the structure and bus transaction types of a regular single-block write command. The transferred data block includes all of the required information for the command (the password setting mode, the PWD itself, and card lock/unlock). The command data block size is defined by the SDIO card host module before it sends the card lock/unlock command, and has the structure shown in [Table 172](#).

The bit settings are as follows:

- ERASE: setting it forces an erase operation. All other bits must be zero, and only the command byte is sent
- LOCK\_UNLOCK: setting it locks the card. LOCK\_UNLOCK can be set simultaneously with SET\_PWD, however not with CLR\_PWD
- CLR\_PWD: setting it clears the password data
- SET\_PWD: setting it saves the password data to memory
- PWD\_LEN: it defines the length of the password in bytes
- PWD: the password (new or currently used, depending on the command)

The following sections list the command sequences to set/reset a password, lock/unlock the card, and force an erase.

### Setting the password

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode, the 8-bit PWD\_LEN, and the number of bytes of the new password.

When a password replacement is done, the block size must take into account that both the old and the new passwords are sent with the command.

3. Send **LOCK/UNLOCK** (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (SET\_PWD = 1), the length (PWD\_LEN), and the password (PWD) itself. When a password replacement is done, the length value (PWD\_LEN) includes the length of both passwords, the old and the new one, and the PWD field includes the old password (currently used) followed by the new password.
4. When the password is matched, the new password and its size are saved into the PWD and PWD\_LEN fields, respectively. When the old password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the password is not changed.

The password length field (PWD\_LEN) indicates whether a password is currently set. When this field is nonzero, there is a password set and the card locks itself after power-up. It is possible to lock the card immediately in the current power session by setting the LOCK\_UNLOCK bit (while setting the password) or sending an additional command for card locking.

### Resetting the password

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode, the 8-bit PWD\_LEN, and the number of bytes in the currently used password.
3. Send **LOCK/UNLOCK** (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (CLR\_PWD = 1), the length (PWD\_LEN) and the password (PWD) itself. The LOCK\_UNLOCK bit is ignored.
4. When the password is matched, the PWD field is cleared and PWD\_LEN is set to 0. When the password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the password is not changed.

### Locking a card

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit card lock/unlock mode (byte 0 in [Table 172](#)), the 8-bit PWD\_LEN, and the number of bytes of the current password.
3. Send **LOCK/UNLOCK** (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (LOCK\_UNLOCK = 1), the length (PWD\_LEN), and the password (PWD) itself.
4. When the password is matched, the card is locked and the CARD\_IS\_LOCKED status bit is set in the card status register. When the password sent does not correspond (in size and/or content) to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the lock fails.

It is possible to set the password and to lock the card in the same sequence. In this case, the SDIO card host module performs all the required steps for setting the password (see [Setting the password on page 1043](#)), however it is necessary to set the LOCK\_UNLOCK bit in Step 3 when the new password command is sent.

When the password is previously set (PWD\_LEN is not 0), the card is locked automatically after power-on reset. An attempt to lock a locked card or to lock a card that does not have a password fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### Unlocking the card

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Define the block length (SET\_BLOCKLEN, CMD16) to send, given by the 8-bit cardlock/unlock mode (byte 0 in [Table 172](#)), the 8-bit PWD\_LEN, and the number of bytes of the current password.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data block size on the data line including the 16-bit CRC. The data block indicates the mode (LOCK\_UNLOCK = 0), the length (PWD\_LEN), and the password (PWD) itself.
4. When the password is matched, the card is unlocked and the CARD\_IS\_LOCKED status bit is cleared in the card status register. When the password sent is not correct in size and/or content and does not correspond to the expected password, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register, and the card remains locked.

The unlocking function is only valid for the current power session. When the PWD field is not clear, the card is locked automatically on the next power-up.

An attempt to unlock an unlocked card fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

### Forcing erase

If the user has forgotten the password (PWD content), it is possible to access the card after clearing all the data on the card. This forced erase operation erases all card data and all password data.

1. Select a card (SELECT/DESELECT\_CARD, CMD7), if none is already selected.
2. Set the block length (SET\_BLOCKLEN, CMD16) to 1 byte. Only the 8-bit card lock/unlock byte (byte 0 in [Table 172](#)) is sent.
3. Send LOCK/UNLOCK (CMD42) with the appropriate data byte on the data line including the 16-bit CRC. The data block indicates the mode (ERASE = 1). All other bits must be zero.
4. When the ERASE bit is the only bit set in the data field, all card contents are erased, including the PWD and PWD\_LEN fields, and the card is no longer locked. When any other bits are set, the LOCK\_UNLOCK\_FAILED error bit is set in the card status register and the card retains all of its data, and remains locked.

An attempt to use a force erase on an unlocked card fails and the LOCK\_UNLOCK\_FAILED error bit is set in the card status register.

## 31.4.11 Card status register

The response format R1 contains a 32-bit field named card status. This field is intended to transmit the card status information (which may be stored in a local status register) to the host. If not specified otherwise, the status entries are always related to the previously issued command.

[Table 159](#) defines the different entries of the status. The type and clear condition fields in the table are abbreviated as follows:

Type:

- E: error bit
- S: status bit
- R: detected and set for the actual command response
- X: detected and set during command execution. The SDIO card host must poll the card by issuing the status command to read these bits.

Clear condition:

- A: according to the card current state
- B: always related to the previous command. Reception of a valid command clears it (with a delay of one command)
- C: clear by read

**Table 159. Card status**

| Bits | Identifier           | Type  | Value                       | Description                                                                                                                                                                                                                                                                                                                                                               | Clear condition |
|------|----------------------|-------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 31   | ADDRESS_OUT_OF_RANGE | E R X | '0'= no error<br>'1'= error | The command address argument was out of the allowed range for this card.<br>A multiple block or stream read/write operation is (although started in a valid address) attempting to read or write beyond the card capacity.                                                                                                                                                | C               |
| 30   | ADDRESS_MISALIGN     | -     | '0'= no error<br>'1'= error | The commands address argument (in accordance with the currently set block length) positions the first data block misaligned to the card physical blocks.<br>A multiple block read/write operation (although started with a valid address/block-length combination) is attempting to read or write a data block which is not aligned with the physical blocks of the card. | C               |
| 29   | BLOCK_LEN_ERROR      | -     | '0'= no error<br>'1'= error | Either the argument of a SET_BLOCKLEN command exceeds the maximum value allowed for the card, or the previously defined block length is illegal for the current command (e.g. the host issues a write command, the current block length is smaller than the maximum allowed value for the card and it is not allowed to write partial blocks)                             | C               |
| 28   | ERASE_SEQ_ERROR      | -     | '0'= no error<br>'1'= error | An error in the sequence of erase commands occurred.                                                                                                                                                                                                                                                                                                                      | C               |
| 27   | ERASE_PARAM          | E X   | '0'= no error<br>'1'= error | An invalid selection of erase groups for erase occurred.                                                                                                                                                                                                                                                                                                                  | C               |
| 26   | WP_VIOLATION         | E X   | '0'= no error<br>'1'= error | Attempt to program a write-protected block.                                                                                                                                                                                                                                                                                                                               | C               |

Table 159. Card status (continued)

| Bits | Identifier         | Type | Value                                    | Description                                                                                                                                                                                                                                                                              | Clear condition |
|------|--------------------|------|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| 25   | CARD_IS_LOCKED     | S R  | '0' = card unlocked<br>'1' = card locked | When set, signals that the card is locked by the host                                                                                                                                                                                                                                    | A               |
| 24   | LOCK_UNLOCK_FAILED | E X  | '0' = no error<br>'1' = error            | Set when a sequence or password error has been detected in lock/unlock card command                                                                                                                                                                                                      | C               |
| 23   | COM_CRC_ERROR      | E R  | '0' = no error<br>'1' = error            | The CRC check of the previous command failed.                                                                                                                                                                                                                                            | B               |
| 22   | ILLEGAL_COMMAND    | E R  | '0' = no error<br>'1' = error            | Command not legal for the card state                                                                                                                                                                                                                                                     | B               |
| 21   | CARD_ECC_FAILED    | E X  | '0' = success<br>'1' = failure           | Card internal ECC was applied but failed to correct the data.                                                                                                                                                                                                                            | C               |
| 20   | CC_ERROR           | E R  | '0' = no error<br>'1' = error            | (Undefined by the standard) A card error occurred, which is not related to the host command.                                                                                                                                                                                             | C               |
| 19   | ERROR              | E X  | '0' = no error<br>'1' = error            | (Undefined by the standard) A generic card error related to the (and detected during) execution of the last host command (e.g. read or write failures).                                                                                                                                  | C               |
| 18   | Reserved           |      |                                          |                                                                                                                                                                                                                                                                                          |                 |

### 31.4.12 SD status register

The SD status contains status bits that are related to the SD memory card proprietary features and may be used for future application-specific usage. The size of the SD Status is one data block of 512 bits. The contents of this register are transmitted to the SDIO card host if ACMD13 is sent (CMD55 followed with CMD13). ACMD13 can be sent to a card in transfer state only (card is selected).

[Table 160](#) defines the different entries of the SD status register. The type and clear condition fields in the table are abbreviated as follows:

Type:

- E: error bit
- S: status bit
- R: detected and set for the actual command response
- X: detected and set during command execution. The SDIO card Host must poll the card by issuing the status command to read these bits

Clear condition:

- A: according to the card current state
- B: always related to the previous command. Reception of a valid command clears it (with a delay of one command)
- C: clear by read

**Table 160. SD status**

| 311:0    | Reserved for Manufacturer |      |                                                                                                                                                                                              |                                                                                                                                                                                                                                       |                 |

**SIZE\_OF\_PROTECTED\_AREA**

Setting this field differs between standard- and high-capacity cards. In the case of a standard-capacity card, the capacity of protected area is calculated as follows:

$$\text{Protected area} = \text{SIZE\_OF\_PROTECTED\_AREA\_} * \text{MULT} * \text{BLOCK\_LEN.}$$

SIZE\_OF\_PROTECTED\_AREA is specified by the unit in MULT\*BLOCK\_LEN.

In the case of a high-capacity card, the capacity of protected area is specified in this field:

$$\text{Protected area} = \text{SIZE\_OF\_PROTECTED\_AREA}$$

SIZE\_OF\_PROTECTED\_AREA is specified by the unit in bytes.

**SPEED\_CLASS**

This 8-bit field indicates the speed class and the value can be calculated by  $P_W/2$  (where  $P_W$  is the write performance).

**Table 161. Speed class code field**

| <b>SPEED_CLASS</b> | <b>Value definition</b> |
|--------------------|-------------------------|
| 00h                | Class 0                 |
| 01h                | Class 2                 |
| 02h                | Class 4                 |
| 03h                | Class 6                 |
| 04h – FFh          | Reserved                |

**PERFORMANCE\_MOVE**

This 8-bit field indicates Pm (performance move) and the value can be set by 1 [MB/sec] steps. If the card does not move used RUs (recording units), Pm should be considered as infinity. Setting the field to FFh means infinity.

**Table 162. Performance move field**

| <b>PERFORMANCE_MOVE</b> | <b>Value definition</b> |
|-------------------------|-------------------------|
| 00h                     | Not defined             |
| 01h                     | 1 [MB/sec]              |
| 02h                     | 02h 2 [MB/sec]          |
| -----                   | -----                   |
| FEh                     | 254 [MB/sec]            |
| FFh                     | Infinity                |

**AU\_SIZE**

This 4-bit field indicates the AU size and the value can be selected in the power of 2 base from 16 KB.

**Table 163. AU\_SIZE field**

| AU_SIZE | Value definition |
|---------|------------------|
| 00h     | Not defined      |
| 01h     | 16 KB            |
| 02h     | 32 KB            |
| 03h     | 64 KB            |
| 04h     | 128 KB           |
| 05h     | 256 KB           |
| 06h     | 512 KB           |
| 07h     | 1 MB             |
| 08h     | 2 MB             |
| 09h     | 4 MB             |
| Ah – Fh | Reserved         |

The maximum AU size, which depends on the card capacity, is defined in [Table 164](#). The card can be set to any AU size between RU size and maximum AU size.

**Table 164. Maximum AU size**

| Capacity        | 16 MB-64 MB | 128 MB-256 MB | 512 MB | 1 GB-32 GB |
|-----------------|-------------|---------------|--------|------------|
| Maximum AU Size | 512 KB      | 1 MB          | 2 MB   | 4 MB       |

**ERASE\_SIZE**

This 16-bit field indicates NERASE. When NERASE numbers of AUs are erased, the timeout value is specified by ERASE\_TIMEOUT (Refer to [ERASE\\_TIMEOUT](#)). The host should determine the proper number of AUs to be erased in one operation so that the host can show the progress of the erase operation. If this field is set to 0, the erase timeout calculation is not supported.

**Table 165. Erase size field**

| ERASE_SIZE | Value definition                            |
|------------|---------------------------------------------|
| 0000h      | Erase timeout calculation is not supported. |
| 0001h      | 1 AU                                        |
| 0002h      | 2 AU                                        |
| 0003h      | 3 AU                                        |
| -----      | -----                                       |
| FFFFh      | 65535 AU                                    |

**ERASE\_TIMEOUT**

This 6-bit field indicates **TERASE** and the value indicates the erase timeout from offset when multiple AUs are being erased as specified by **ERASE\_SIZE**. The range of **ERASE\_TIMEOUT** can be defined as up to 63 seconds and the card manufacturer can choose any combination of **ERASE\_SIZE** and **ERASE\_TIMEOUT** depending on the implementation. Determining **ERASE\_TIMEOUT** determines the **ERASE\_SIZE**.

**Table 166. Erase timeout field**

| <b>ERASE_TIMEOUT</b> | <b>Value definition</b>                     |
|----------------------|---------------------------------------------|
| 00                   | Erase timeout calculation is not supported. |
| 01                   | 1 [sec]                                     |
| 02                   | 2 [sec]                                     |
| 03                   | 3 [sec]                                     |
| -----                | -----                                       |
| 63                   | 63 [sec]                                    |

**ERASE\_OFFSET**

This 2-bit field indicates **TOFFSET** and one of four values can be selected. This field is meaningless if the **ERASE\_SIZE** and **ERASE\_TIMEOUT** fields are set to 0.

**Table 167. Erase offset field**

| <b>ERASE_OFFSET</b> | <b>Value definition</b> |
|---------------------|-------------------------|
| 0h                  | 0 [sec]                 |
| 1h                  | 1 [sec]                 |
| 2h                  | 2 [sec]                 |
| 3h                  | 3 [sec]                 |

**31.4.13 SD I/O mode****SD I/O interrupts**

To allow the SD I/O card to interrupt the MultiMediaCard/SD module, an interrupt function is available on a pin on the SD interface. Pin 8, used as **SDIO\_D1** when operating in the 4-bit SD mode, signals the cards interrupt to the MultiMediaCard/SD module. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the MultiMediaCard/SD module or deasserted due to the end of the interrupt period. After the MultiMediaCard/SD module has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card's internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (**SDIO\_D[3:0]**). The MultiMediaCard/SD module samples the level of pin 8 (**SDIO\_D/IRQ**) into the interrupt detector only during the interrupt period. At all other times, the MultiMediaCard/SD module ignores this value.

The interrupt period is applicable for both memory and I/O operations. The definition of the interrupt period for operations with single blocks is different from the definition for multiple-block data transfers.

### SD I/O suspend and resume

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the MMC/SD bus. To share access to the MMC/SD module among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the MMC/SD module can temporarily halt a data transfer operation to one function or memory (suspend) to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is resumed (restarted) where it left off. Support of suspend/resume is optional on a per-card basis. To perform the suspend/resume operation on the MMC/SD bus, the MMC/SD module performs the following steps:

1. Determines the function currently using the SDIO\_D [3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

### SD I/O ReadWait

The optional ReadWait (RW) operation is defined only for the SD 1-bit and 4-bit modes. The ReadWait operation allows the MMC/SD module to signal a card that it is reading multiple registers (IO\_RW\_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the MMC/SD module to send commands to any function within the SD I/O device. To determine when a card supports the ReadWait protocol, the MMC/SD module must test capability bits in the internal card registers. The timing for ReadWait is based on the interrupt period.

## 31.4.14 Commands and responses

### Application-specific and general commands

The SD card host module system is designed to provide a standard interface for a variety of applications types. In this environment, there is a need for specific customer/application features. To implement these features, two types of generic commands are defined in the standard: application-specific commands (ACMD) and general commands (GEN\_CMD).

When the card receives the APP\_CMD (CMD55) command, the card expects the next command to be an application-specific command. ACMDs have the same structure as regular MultiMediaCard commands and can have the same CMD number. The card recognizes it as ACMD because it appears after APP\_CMD (CMD55). When the command immediately following the APP\_CMD (CMD55) is not a defined application-specific command, the standard command is used. For example, when the card has a definition for SD\_STATUS (ACMD13), and receives CMD13 immediately following APP\_CMD (CMD55), this is interpreted as SD\_STATUS (ACMD13). However, when the card receives CMD7 immediately following APP\_CMD (CMD55) and the card does not have a definition for ACMD7, this is interpreted as the standard (SELECT/DESELECT\_CARD) CMD7.

To use one of the manufacturer-specific ACMDs the SD card Host must perform the following steps:

1. Send APP\_CMD (CMD55)  
The card responds to the MultiMediaCard/SD module, indicating that the APP\_CMD bit is set and an ACMD is now expected.
2. Send the required ACMD  
The card responds to the MultiMediaCard/SD module, indicating that the APP\_CMD bit is set and that the accepted command is interpreted as an ACMD. When a nonACMD is sent, it is handled by the card as a normal MultiMediaCard command and the APP\_CMD bit in the card status register stays clear.

When an invalid command is sent (neither ACMD nor CMD) it is handled as a standard MultiMediaCard illegal command error.

The bus transaction for a GEN\_CMD is the same as the single-block read or write commands (WRITE\_BLOCK, CMD24 or READ\_SINGLE\_BLOCK, CMD17). In this case, the argument denotes the direction of the data transfer rather than the address, and the data block has vendor-specific format and meaning.

The card must be selected (in transfer state) before sending GEN\_CMD (CMD56). The data block size is defined by SET\_BLOCKLEN (CMD16). The response to GEN\_CMD (CMD56) is in R1b format.

### Command types

Both application-specific and general commands are divided into the four following types:

- **broadcast command (BC):** sent to all cards; no responses returned.
- **broadcast command with response (BCR):** sent to all cards; responses received from all cards simultaneously.
- **addressed (point-to-point) command (AC):** sent to the card that is selected; does not include a data transfer on the SDIO\_D line(s).
- **addressed (point-to-point) data transfer command (ADTC):** sent to the card that is selected; includes a data transfer on the SDIO\_D line(s).

### Command formats

See [Table 152 on page 1030](#) for command formats.

### Commands for the MultiMediaCard/SD module

**Table 168. Block-oriented write commands**

| CMD index | Type | Argument                                    | Response format | Abbreviation    | Description                                                                                                              |
|-----------|------|---------------------------------------------|-----------------|-----------------|--------------------------------------------------------------------------------------------------------------------------|
| CMD23     | ac   | [31:16] set to 0<br>[15:0] number of blocks | R1              | SET_BLOCK_COUNT | Defines the number of blocks which are going to be transferred in the multiple-block read or write command that follows. |
| CMD24     | adtc | [31:0] data address                         | R1              | WRITE_BLOCK     | Writes a block of the size selected by the SET_BLOCKLEN command.                                                         |

Table 168. Block-oriented write commands (continued)

| CMD index | Type | Argument            | Response format | Abbreviation         | Description                                                                                                                                                                                                                            |
|-----------|------|---------------------|-----------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD25     | adtc | [31:0] data address | R1              | WRITE_MULTIPLE_BLOCK | Continuously writes blocks of data until a STOP_TRANSMISSION follows or the requested number of blocks has been received.                                                                                                              |
| CMD26     | adtc | [31:0] stuff bits   | R1              | PROGRAM_CID          | Programming of the card identification register. This command must be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for manufacturer. |
| CMD27     | adtc | [31:0] stuff bits   | R1              | PROGRAM_CSD          | Programming of the programmable bits of the CSD.                                                                                                                                                                                       |

Table 169. Block-oriented write protection commands

| CMD index | Type     | Argument                          | Response format | Abbreviation    | Description                                                                                                                                                                                         |
|-----------|----------|-----------------------------------|-----------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD28     | ac       | [31:0] data address               | R1b             | SET_WRITE_PROT  | If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card-specific data (WP_GRP_SIZE). |
| CMD29     | ac       | [31:0] data address               | R1b             | CLR_WRITE_PROT  | If the card provides write protection features, this command clears the write protection bit of the addressed group.                                                                                |
| CMD30     | adtc     | [31:0] write protect data address | R1              | SEND_WRITE_PROT | If the card provides write protection features, this command asks the card to send the status of the write protection bits.                                                                         |
| CMD31     | Reserved |                                   |                 |                 |                                                                                                                                                                                                     |

Table 170. Erase commands

| CMD index             | Type                                                                                                                                  | Argument            | Response format | Abbreviation      | Description                                                                                  |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------|---------------------|-----------------|-------------------|----------------------------------------------------------------------------------------------|
| CMD32<br>...<br>CMD34 | Reserved. These command indexes cannot be used in order to maintain backward compatibility with older versions of the MultiMediaCard. |                     |                 |                   |                                                                                              |
| CMD35                 | ac                                                                                                                                    | [31:0] data address | R1              | ERASE_GROUP_START | Sets the address of the first erase group within a range to be selected for erase.           |
| CMD36                 | ac                                                                                                                                    | [31:0] data address | R1              | ERASE_GROUP_END   | Sets the address of the last erase group within a continuous range to be selected for erase. |

Table 170. Erase commands (continued)

| CMD index | Type                                                                                                                               | Argument          | Response format | Abbreviation | Description                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------|-------------------|-----------------|--------------|----------------------------------------------|
| CMD37     | Reserved. This command index cannot be used in order to maintain backward compatibility with older versions of the MultiMediaCards |                   |                 |              |                                              |
| CMD38     | ac                                                                                                                                 | [31:0] stuff bits | R1              | ERASE        | Erases all previously selected write blocks. |

Table 171. I/O mode commands

| CMD index | Type     | Argument                                                                                     | Response format | Abbreviation | Description                                                                                                                                                                                                                                                                                                                             |
|-----------|----------|----------------------------------------------------------------------------------------------|-----------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD39     | ac       | [31:16] RCA<br>[15:15] register write flag<br>[14:8] register address<br>[7:0] register data | R4              | FAST_IO      | Used to write and read 8-bit (register) data fields. The command addresses a card and a register and provides the data for writing if the write flag is set. The R4 response contains data read from the addressed register. This command accesses application-dependent registers that are not defined in the MultiMediaCard standard. |
| CMD40     | bcr      | [31:0] stuff bits                                                                            | R5              | GO_IRQ_STATE | Places the system in the interrupt mode.                                                                                                                                                                                                                                                                                                |
| CMD41     | Reserved |                                                                                              |                 |              |                                                                                                                                                                                                                                                                                                                                         |

Table 172. Lock card

| CMD index             | Type     | Argument          | Response format | Abbreviation | Description                                                                                                         |
|-----------------------|----------|-------------------|-----------------|--------------|---------------------------------------------------------------------------------------------------------------------|
| CMD42                 | adtc     | [31:0] stuff bits | R1b             | LOCK_UNLOCK  | Sets/resets the password or locks/unlocks the card. The size of the data block is set by the SET_BLOCK_LEN command. |
| CMD43<br>...<br>CMD54 | Reserved |                   |                 |              |                                                                                                                     |

Table 173. Application-specific commands

| CMD index | Type | Argument                         | Response format | Abbreviation | Description                                                                                                                                                                                              |
|-----------|------|----------------------------------|-----------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CMD55     | ac   | [31:16] RCA<br>[15:0] stuff bits | R1              | APP_CMD      | Indicates to the card that the next command bits is an application specific command rather than a standard command                                                                                       |
| CMD56     | adtc | [31:1] stuff bits<br>[0]: RD/WR  | -               | -            | Used either to transfer a data block to the card or to get a data block from the card for general purpose/application-specific commands. The size of the data block is set by the SET_BLOCK_LEN command. |

Table 173. Application-specific commands (continued)

| CMD index             | Type                       | Argument | Response format | Abbreviation | Description |
|-----------------------|----------------------------|----------|-----------------|--------------|-------------|
| CMD57<br>...<br>CMD59 | Reserved.                  |          |                 |              |             |
| CMD60<br>...<br>CMD63 | Reserved for manufacturer. |          |                 |              |             |

## 31.5 Response formats

All responses are sent via the MCCMD command line SDIO\_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. All responses, except for the R3 response type, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

There are five types of responses. Their formats are defined as follows:

### 31.5.1 R1 (normal response command)

Code length = 48 bits. The 45:40 bits indicate the index of the command to be responded to, this value being interpreted as a binary-coded number (between 0 and 63). The status of the card is coded in 32 bits.

Table 174. R1 response

| Bit position | Width (bits) | Value | Description      |
|--------------|--------------|-------|------------------|
| 47           | 1            | 0     | Start bit        |
| 46           | 1            | 0     | Transmission bit |
| [45:40]      | 6            | X     | Command index    |
| [39:8]       | 32           | X     | Card status      |
| [7:1]        | 7            | X     | CRC7             |
| 0            | 1            | 1     | End bit          |

### 31.5.2 R1b

It is identical to R1 with an optional busy signal transmitted on the data line. The card may become busy after receiving these commands based on its state prior to the command reception.

### 31.5.3 R2 (CID, CSD register)

Code length = 136 bits. The contents of the CID register are sent as a response to the CMD2 and CMD10 commands. The contents of the CSD register are sent as a response to

CMD9. Only the bits [127...1] of the CID and CSD are transferred, the reserved bit [0] of these registers is replaced by the end bit of the response. The card indicates that an erase is in progress by holding MCDAT low. The actual erase time may be quite long, and the host may issue CMD7 to deselect the card.

Table 175. R2 response

| Bit position | Width (bits) | Value    | Description      |
|--------------|--------------|----------|------------------|
| 135          | 1            | 0        | Start bit        |
| 134          | 1            | 0        | Transmission bit |
| [133:128]    | 6            | '111111' | Command index    |
| [127:1]      | 127          | X        | Card status      |
| 0            | 1            | 1        | End bit          |

### 31.5.4 R3 (OCR register)

Code length: 48 bits. The contents of the OCR register are sent as a response to CMD1. The level coding is as follows: restricted voltage windows = low, card busy = low.

Table 176. R3 response

| Bit position | Width (bits) | Value     | Description      |
|--------------|--------------|-----------|------------------|
| 47           | 1            | 0         | Start bit        |
| 46           | 1            | 0         | Transmission bit |
| [45:40]      | 6            | '111111'  | Reserved         |
| [39:8]       | 32           | X         | OCR register     |
| [7:1]        | 7            | '1111111' | Reserved         |
| 0            | 1            | 1         | End bit          |

### 31.5.5 R4 (Fast I/O)

Code length: 48 bits. The argument field contains the RCA of the addressed card, the register address to be read from or written to, and its content.

Table 177. R4 response

| Bit position          |         | Width (bits) | Value    | Description            |
|-----------------------|---------|--------------|----------|------------------------|
| 47                    |         | 1            | 0        | Start bit              |
| 46                    |         | 1            | 0        | Transmission bit       |
| [45:40]               |         | 6            | ‘100111’ | CMD39                  |
| [39:8] Argument field | [31:16] | 16           | X        | RCA                    |
|                       | [15:8]  | 8            | X        | register address       |
|                       | [7:0]   | 8            | X        | read register contents |

Table 177. R4 response (continued)

| Bit position | Width (bits) | Value | Description |
|--------------|--------------|-------|-------------|
| [7:1]        | 7            | X     | CRC7        |
| 0            | 1            | 1     | End bit     |

### 31.5.6 R4b

For SD I/O only: an SDIO card receiving the CMD5 responds with a unique SDIO response R4. The format is:

Table 178. R4b response

| Bit position          |         | Width (bits) | Value | Description             |
|-----------------------|---------|--------------|-------|-------------------------|
| 47                    |         | 1            | 0     | Start bit               |
| 46                    |         | 1            | 0     | Transmission bit        |
| [45:40]               |         | 6            | x     | Reserved                |
| [39:8] Argument field | 39      | 16           | X     | Card is ready           |
|                       | [38:36] | 3            | X     | Number of I/O functions |
|                       | 35      | 1            | X     | Present memory          |
|                       | [34:32] | 3            | X     | Stuff bits              |
|                       | [31:8]  | 24           | X     | I/O ORC                 |
| [7:1]                 |         | 7            | X     | Reserved                |
| 0                     |         | 1            | 1     | End bit                 |

Once an SD I/O card has received a CMD5, the I/O portion of that card is enabled to respond normally to all further commands. This I/O enable of the function within the I/O card remains set until a reset, power cycle or CMD52 with write to I/O reset is received by the card. Note that an SD memory-only card may respond to a CMD5. The proper response for a memory-only card would be *Present memory* = 1 and *Number of I/O functions* = 0. A memory-only card built to meet the SD Memory Card specification version 1.0 would detect the CMD5 as an illegal command and not respond. The I/O aware host sends CMD5. If the card responds with response R4, the host determines the card's configuration based on the data contained within the R4 response.

### 31.5.7 R5 (interrupt request)

Only for MultiMediaCard. Code length: 48 bits. If the response is generated by the host, the RCA field in the argument is 0x0.

Table 179. R5 response

| Bit position | Width (bits) | Value    | Description      |
|--------------|--------------|----------|------------------|
| 47           | 1            | 0        | Start bit        |
| 46           | 1            | 0        | Transmission bit |
| [45:40]      | 6            | '101000' | CMD40            |

Table 179. R5 response (continued)

| Bit position          |         | Width (bits) | Value | Description                                |
|-----------------------|---------|--------------|-------|--------------------------------------------|
| [39:8] Argument field | [31:16] | 16           | X     | RCA [31:16] of winning card or of the host |
|                       | [15:0]  | 16           | X     | Not defined. May be used for IRQ data      |
| [7:1]                 |         | 7            | X     | CRC7                                       |
| 0                     |         | 1            | 1     | End bit                                    |

### 31.5.8 R6

Only for SD I/O. The normal response to CMD3 by a memory device. It is shown in [Table 180](#).

Table 180. R6 response

| Bit position          |         | Width (bits) | Value    | Description                                |
|-----------------------|---------|--------------|----------|--------------------------------------------|
| 47                    |         | 1            | 0        | Start bit                                  |
| 46                    |         | 1            | 0        | Transmission bit                           |
| [45:40]               |         | 6            | '101000' | CMD40                                      |
| [39:8] Argument field | [31:16] | 16           | X        | RCA [31:16] of winning card or of the host |
|                       | [15:0]  | 16           | X        | Not defined. May be used for IRQ data      |
| [7:1]                 |         | 7            | X        | CRC7                                       |
| 0                     |         | 1            | 1        | End bit                                    |

The card [23:8] status bits are changed when CMD3 is sent to an I/O-only card. In this case, the 16 bits of response are the SD I/O-only values:

- Bit [15] COM\_CRC\_ERROR
- Bit [14] ILLEGAL\_COMMAND
- Bit [13] ERROR
- Bits [12:0] Reserved

## 31.6 SDIO I/O card-specific operations

The following features are SD I/O-specific operations:

- SDIO read wait operation by SDIO\_D2 signalling
- SDIO read wait operation by stopping the clock
- SDIO suspend/resume operation (write and read suspend)
- SDIO interrupts

The SDIO supports these operations only if the SDIO\_DCTRL[11] bit is set, except for read suspend that does not need specific hardware implementation.

### 31.6.1 SDIO I/O read wait operation by SDIO\_D2 signaling

It is possible to start the readwait interval before the first block is received: when the data path is enabled (SDIO\_DCTRL[0] bit set), the SDIO-specific operation is enabled (SDIO\_DCTRL[11] bit set), read wait starts (SDIO\_DCTRL[10] = 0 and SDIO\_DCTRL[8] = 1) and data direction is from card to SDIO (SDIO\_DCTRL[1] = 1), the DPSM directly moves from Idle to Readwait. In Readwait the DPSM drives SDIO\_D2 to 0 after 2 SDIO\_CK clock cycles. In this state, when you set the RWSTOP bit (SDIO\_DCTRL[9]), the DPSM remains in Wait for two more SDIO\_CK clock cycles to drive SDIO\_D2 to 1 for one clock cycle (in accordance with SDIO specification). The DPSM then starts waiting again until it receives data from the card. The DPSM does not start a readwait interval while receiving a block even if read wait start is set: the readwait interval starts after the CRC is received. The RWSTOP bit has to be cleared to start a new read wait operation. During the readwait interval, the SDIO can detect SDIO interrupts on SDIO\_D1.

### 31.6.2 SDIO read wait operation by stopping SDIO\_CK

If the SDIO card does not support the previous read wait method, the SDIO can perform a read wait by stopping SDIO\_CK (SDIO\_DCTRL is set just like in the method presented in [Section 31.6.1](#), but SDIO\_DCTRL[10] = 1): DPSM stops the clock two SDIO\_CK cycles after the end bit of the current received block and starts the clock again after the read wait start bit is set.

As SDIO\_CK is stopped, any command can be issued to the card. During a read/wait interval, the SDIO can detect SDIO interrupts on SDIO\_D1.

### 31.6.3 SDIO suspend/resume operation

While sending data to the card, the SDIO can suspend the write operation. the SDIO\_CMD[11] bit is set and indicates to the CPSM that the current command is a suspend command. The CPSM analyzes the response and when the ACK is received from the card (suspend accepted), it acknowledges the DPSM that goes Idle after receiving the CRC token of the current block.

The hardware does not save the number of the remaining block to be sent to complete the suspended operation (resume).

The write operation can be suspended by software, just by disabling the DPSM (SDIO\_DCTRL[0] = 0) when the ACK of the suspend command is received from the card. The DPSM enters then the Idle state.

To suspend a read: the DPSM waits in the Wait\_r state as the function to be suspended sends a complete packet just before stopping the data transaction. The application continues reading RxFIFO until the FIFO is empty, and the DPSM goes Idle automatically.

### 31.6.4 SDIO interrupts

SDIO interrupts are detected on the SDIO\_D1 line once the SDIO\_DCTRL[11] bit is set.

## 31.7 CE-ATA specific operations

The following features are CE-ATA specific operations:

- sending the command completion signal disable to the CE-ATA device
- receiving the command completion signal from the CE-ATA device
- signaling the completion of the CE-ATA command to the CPU, using the status bit and/or interrupt.

The SDIO supports these operations only for the CE-ATA CMD61 command, that is, if SDIO\_CMD[14] is set.

### 31.7.1 Command completion signal disable

Command completion signal disable is sent 8 bit cycles after the reception of a **short** response if the 'enable CMD completion' bit, SDIO\_CMD[12], is not set and the 'not interrupt Enable' bit, SDIO\_CMD[13], is set.

The CPSM enters the Pend state, loading the command shift register with the disable sequence "00001" and, the command counter with 43. Eight cycles after, a trigger moves the CPSM to the Send state. When the command counter reaches 48, the CPSM becomes Idle as no response is awaited.

### 31.7.2 Command completion signal enable

If the 'enable CMD completion' bit SDIO\_CMD[12] is set and the 'not interrupt Enable' bit SDIO\_CMD[13] is set, the CPSM waits for the command completion signal in the Waitcpl state.

When '0' is received on the CMD line, the CPSM enters the Idle state. No new command can be sent for 7 bit cycles. Then, for the last 5 cycles (out of the 7) the CMD line is driven to '1' in push-pull mode.

### 31.7.3 CE-ATA interrupt

The command completion is signaled to the CPU by the status bit SDIO\_STA[23]. This static bit can be cleared with the clear bit SDIO\_ICR[23].

The SDIO\_STA[23] status bit can generate an interrupt on each interrupt line, depending on the mask bit SDIO\_MASKx[23].

### 31.7.4 Aborting CMD61

If the command completion disable signal has not been sent and CMD61 needs to be aborted, the command state machine must be disabled. It then becomes Idle, and the CMD12 command can be sent. No command completion disable signal is sent during the operation.

## 31.8 HW flow control

The HW flow control functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDIO\_CLK and freeze SDIO state machines. The data transfer is stalled while the FIFO is unable to transmit or receive data. Only state machines clocked by SDIOCLK are frozen, the APB2 interface is still alive. The FIFO can thus be filled or emptied even if flow control is activated.

To enable HW flow control, the SDIO\_CLKCR[14] register bit must be set to 1. After reset Flow Control is disabled.

## 31.9 SDIO registers

The device communicates to the system via 32-bit-wide control registers accessible via APB2.

The peripheral registers have to be accessed by words (32 bits).

### 31.9.1 SDIO power control register (SDIO\_POWER)

Address offset: 0x00

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |      |   |     |   |  |  |  |  |  |  |  |  |  |  |  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|------|---|-----|---|--|--|--|--|--|--|--|--|--|--|--|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3    | 2 | 1   | 0 |  |  |  |  |  |  |  |  |  |  |  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | PWRC |   | TRL |   |  |  |  |  |  |  |  |  |  |  |  |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | rw   |   | rw  |   |  |  |  |  |  |  |  |  |  |  |  |

Bits 31:2 Reserved, must be kept at reset value

Bits 1:0 **PWRCTRL**: Power supply control bits.

These bits are used to define the current functional state of the card clock:

00: Power-off: the clock to card is stopped.

01: Reserved

10: Reserved power-up

11: Power-on: the card is clocked.

**Note:** *At least seven HCLK clock periods are needed between two write accesses to this register. After a data write, data cannot be written to this register for three SDIOCLK clock periods plus two PCLK2 clock periods.*

### 31.9.2 SDI clock control register (SDIO\_CLKCR)

Address offset: 0x04

Reset value: 0x0000 0000

The SDIO\_CLKCR register controls the SDIO\_CK output clock.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14      | 13      | 12      | 11  | 10     | 9      | 8     | 7      | 6   | 5   | 4   | 3   | 2   | 1   | 0   |     |     |  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---------|---------|---------|-----|--------|--------|-------|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|--|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | HWFC_EN | NEGEDGE | WID BUS |     | BYPASS | PWRSAP | CLKEN | CLKDIV |     |     |     |     |     |     |     |     |     |  |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r/w     | r/w     | r/w     | r/w | r/w    | r/w    | r/w   | r/w    | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |  |

Bits 31:15 Reserved, must be kept at reset value

Bit 14 **HWFC\_EN**: HW Flow Control enable

0b: HW Flow Control is disabled

1b: HW Flow Control is enabled

When HW Flow Control is enabled, the meaning of the TXFIFOE and RXFIFOE interrupt signals, see SDIO Status register definition in [Section 31.9.11](#).

Bit 13 **NEGEDGE**:SDIO\_CK dephasing selection bit

0b: SDIO\_CK generated on the rising edge of the master clock SDIOCLK

1b: SDIO\_CK generated on the falling edge of the master clock SDIOCLK

Bits 12:11 **WIDBUS**: Wide bus mode enable bit

00: Default bus mode: SDIO\_D0 used

01: 4-wide bus mode: SDIO\_D[3:0] used

10: 8-wide bus mode: SDIO\_D[7:0] used

Bit 10 **BYPASS**: Clock divider bypass enable bit

0: Disable bypass: SDIOCLK is divided according to the CLKDIV value before driving the SDIO\_CK output signal.

1: Enable bypass: SDIOCLK directly drives the SDIO\_CK output signal.

Bit 9 **PWRSAP**: Power saving configuration bit

For power saving, the SDIO\_CK clock output can be disabled when the bus is idle by setting PWRSAP:

0: SDIO\_CK clock is always enabled

1: SDIO\_CK is only enabled when the bus is active

Bit 8 **CLKEN**: Clock enable bit

0: SDIO\_CK is disabled

1: SDIO\_CK is enabled

Bits 7:0 **CLKDIV**: Clock divide factor

This field defines the divide factor between the input clock (SDIOCLK) and the output clock (SDIO\_CK):  $SDIO\_CK\ frequency = SDIOCLK / [CLKDIV + 2]$ .

*Note:* In order to have a duty cycle of 50% it is recommended to select even values of CLKDIV.

**Note:** While the SD/SDIO card or MultiMediaCard is in identification mode, the SDIO\_CLK frequency must be less than 400 kHz.

The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.

After a data write, data cannot be written to this register for three SDIOCLK clock periods plus two PCLK2 clock periods. SDIO\_CLK can also be stopped during the read wait interval for SD I/O cards: in this case the SDIO\_CLKCR register does not control SDIO\_CLK.

### 31.9.3 SDIO argument register (SDIO\_ARG)

Address offset: 0x08

Reset value: 0x0000 0000

The SDIO\_ARG register contains a 32-bit command argument, which is sent to a card as part of a command message.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CMDARG |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW     | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **CMDARG**: Command argument

Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

### 31.9.4 SDIO command register (SDIO\_CMD)

Address offset: 0x0C

Reset value: 0x0000 0000

The SDIO\_CMD register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |      |            |             |        |          |         |          |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|------|------------|-------------|--------|----------|---------|----------|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14        | 13   | 12         | 11          | 10     | 9        | 8       | 7        | 6        | 5  | 4  | 3  | 2  | 1  | 0  |    |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | CE-ATACMD | nIEN | ENCMDcompl | SDIOSuspend | CPSMEN | WAITPEND | WAITINT | WAITRESP | CMDINDEX |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rW        | rW   | rW         | rW          | rW     | rW       | rW      | rW       | rW       | rW | rW | rW | rW | rW | rW | rW |

Bits 31:15 Reserved, must be kept at reset value

Bit 14 **ATACMD**: CE-ATA command

If ATACMD is set, the CPSM transfers CMD61.

Bit 13 **nIEN**: not Interrupt Enable

if this bit is 0, interrupts in the CE-ATA device are enabled.

Bit 12 **ENCMDcompl**: Enable CMD completion

If this bit is set, the command completion signal is enabled.

Bit 11 **SDIOSuspend**: SD I/O suspend command

If this bit is set, the command to be sent is a suspend command (to be used only with SDIO card).

Bit 10 **CPSMEN**: Command path state machine (CPSM) Enable bit

If this bit is set, the CPSM is enabled.

Bit 9 **WAITPEND**: CPSM Waits for ends of data transfer (CmdPend internal signal).

If this bit is set, the CPSM waits for the end of data transfer before it starts sending a command.

Bit 8 **WAITINT**: CPSM waits for interrupt request

If this bit is set, the CPSM disables command timeout and waits for an interrupt request.

Bits 7:6 **WAITRESP**: Wait for response bits

They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.

00: No response, expect CMDSENT flag

01: Short response, expect CMDREND or CCRCFAIL flag

10: No response, expect CMDSENT flag

11: Long response, expect CMDREND or CCRCFAIL flag

Bits 5:0 **CMDINDEX**: Command index

The command index is sent to the card as part of a command message.

**Note:** After a data write, data cannot be written to this register for three SDIOCLK clock periods plus two PCLK2 clock periods.

MultiMediaCards can send two kinds of response: short responses, 48 bits long, or long responses, 136 bits long. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the sent command. CE-ATA devices send only short responses.

### 31.9.5 SDIO command response register (SDIO\_RESPCMD)

Address offset: 0x10

Reset value: 0x0000 0000

The SDIO\_RESPCMD register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |         |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---------|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7       | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | RESPCMD |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | r       | r | r | r | r | r |   |   |

Bits 31:6 Reserved, must be kept at reset value

Bits 5:0 **RESPCMD**: Response command index

Read-only bit field. Contains the command index of the last command response received.

### 31.9.6 SDIO response 1..4 register (SDIO\_RESPx)

Address offset:  $(0x10 + (4 \times x))$ ;  $x = 1..4$

Reset value: 0x0000 0000

The SDIO\_RESP1/2/3/4 registers contain the status of a card, which is part of the received response.

Bits 31:0 **CARDSTATUSx**: see [Table 181](#).

The Card Status size is 32 or 127 bits, depending on the response type.

**Table 181. Response type and SDIO\_RESPx registers**

| Register   | Short response    | Long response        |
|------------|-------------------|----------------------|
| SDIO_RESP1 | Card Status[31:0] | Card Status [127:96] |
| SDIO_RESP2 | Unused            | Card Status [95:64]  |
| SDIO_RESP3 | Unused            | Card Status [63:32]  |
| SDIO_RESP4 | Unused            | Card Status [31:1]0b |

The most significant bit of the card status is received first. The SDIO\_RESP3 register LSB is always 0b.

### 31.9.7 SDIO data timer register (SDIO\_DTIMER)

Address offset: 0x24

Reset value: 0x0000 0000

The SDIO\_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDIO\_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait\_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

Bits 31:0 **DATETIME**: Data timeout period

Data timeout period expressed in card bus clock periods.

**Note:** A data transfer must be written to the data timer register and the data length register before being written to the data control register.

31.9.8 SDIO data length register (SDIO\_DLEN)

Address offset: 0x28

Reset value: 0x0000 0000

The SDIO\_DLEN register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

Bits 31:25 Reserved, must be kept at reset value

Bits 24:0 **DATALENGTH**: Data length value  
Number of data bytes to be transferred.

*Note:* For a block data transfer, the value in the data length register must be a multiple of the block size (see SDIO\_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.  
For an SDIO multibyte transfer the value in the data length register must be between 1 and 512.

### 31.9.9 SDIO data control register (SDIO\_DCTRL)

Address offset: 0x2C

Reset value: 0x0000 0000

The SDIO\_DCTRL register control the data path state machine (DPSM).

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11     | 10    | 9      | 8       | 7          | 6   | 5   | 4   | 3     | 2      | 1     | 0    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|-------|--------|---------|------------|-----|-----|-----|-------|--------|-------|------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | SDIOEN | RWMOD | RWSTOP | RWSTART | DBLOCKSIZE |     |     |     | DMAEN | DTMODE | DTDIR | DTEN |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r/w    | r/w   | r/w    | r/w     | r/w        | r/w | r/w | r/w | r/w   | r/w    | r/w   | r/w  |

Bits 31:12 Reserved, must be kept at reset value

Bit 11 **SDIOEN**: SD I/O enable functions

If this bit is set, the DPSM performs an SD I/O-card-specific operation.

Bit 10 **RWMOD**: Read wait mode

0: Read Wait control stopping SDIO\_D2

1: Read Wait control using SDIO\_CK

Bit 9 **RWSTOP**: Read wait stop

0: Read wait in progress if RWSTART bit is set

1: Enable for read wait stop if RWSTART bit is set

Bit 8 **RWSTART**: Read wait start

If this bit is set, read wait operation starts.

Bits 7:4 **DBLOCKSIZE**: Data block size

Define the data block length when the block data transfer mode is selected:

0000: (0 decimal) lock length =  $2^0$  = 1 byte

0001: (1 decimal) lock length =  $2^1$  = 2 bytes

0010: (2 decimal) lock length =  $2^2$  = 4 bytes

0011: (3 decimal) lock length =  $2^3$  = 8 bytes

0100: (4 decimal) lock length =  $2^4$  = 16 bytes

0101: (5 decimal) lock length =  $2^5$  = 32 bytes

0110: (6 decimal) lock length =  $2^6$  = 64 bytes

0111: (7 decimal) lock length =  $2^7$  = 128 bytes

1000: (8 decimal) lock length =  $2^8$  = 256 bytes

1001: (9 decimal) lock length =  $2^9$  = 512 bytes

1010: (10 decimal) lock length =  $2^{10}$  = 1024 bytes

1011: (11 decimal) lock length =  $2^{11}$  = 2048 bytes

1100: (12 decimal) lock length =  $2^{12}$  = 4096 bytes

1101: (13 decimal) lock length =  $2^{13}$  = 8192 bytes

1110: (14 decimal) lock length =  $2^{14}$  = 16384 bytes

1111: (15 decimal) reserved

Bit 3 **DMAEN**: DMA enable bit

0: DMA disabled.

1: DMA enabled.

Bit 2 **DTMODE**: Data transfer mode selection 1: Stream or SDIO multibyte data transfer.

- 0: Block data transfer
- 1: Stream or SDIO multibyte data transfer

Bit 1 **DTDIR**: Data transfer direction selection

- 0: From controller to card.
- 1: From card to controller.

Bit 0 **DTEN**: Data transfer enabled bit

Data transfer starts if 1b is written to the DTEN bit. Depending on the direction bit, DTDIR, the DPSM moves to the Wait\_S, Wait\_R state or Readwait if RW Start is set immediately at the beginning of the transfer. It is not necessary to clear the enable bit after the end of a data transfer but the SDIO\_DCTRL must be updated to enable a new data transfer

**Note:** After a data write, data cannot be written to this register for three SDIOCLK clock periods plus two PCLK2 clock periods.

The meaning of the DTMODE bit changes according to the value of the SDIOEN bit. When SDIOEN=0 and DTMODE=1, the MultiMediaCard stream mode is enabled, and when SDIOEN=1 and DTMODE=1, the peripheral enables an SDIO multibyte transfer.

### 31.9.10 SDIO data counter register (SDIO\_DCOUNT)

Address offset: 0x30

Reset value: 0x0000 0000

The SDIO\_DCOUNT register loads the value from the data length register (see SDIO\_DLEN) when the DPSM moves from the Idle state to the Wait\_R or Wait\_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then moves to the Idle state and the data status end flag, DATAEND, is set.

|          |    |    |    |    |    |    |           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24        | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    | DATACOUNT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    | r         | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:25 Reserved, must be kept at reset value

Bits 24:0 **DATACOUNT**: Data count value

When this bit is read, the number of remaining data bytes to be transferred is returned. Write has no effect.

**Note:** This register should be read only when the data transfer is complete.

### 31.9.11 SDIO status register (SDIO\_STA)

Address offset: 0x34

Reset value: 0x0000 0000

The SDIO\_STA register is a read-only register. It contains two types of flag:

- Static flags (bits [23:22,10:0]): these bits remain asserted until they are cleared by writing to the SDIO Interrupt Clear register (see SDIO\_ICR)
- Dynamic flags (bits [21:11]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and deasserted as data while written to the FIFO)

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22     | 21     | 20     | 19      | 18      | 17     | 16     | 15       | 14       | 13    | 12    | 11     | 10      | 9        | 8       | 7       | 6       | 5       | 4        | 3        | 2        | 1        | 0        |
|----------|----|----|----|----|----|----|----|----------|--------|--------|--------|---------|---------|--------|--------|----------|----------|-------|-------|--------|---------|----------|---------|---------|---------|---------|----------|----------|----------|----------|----------|
| Reserved |    |    |    |    |    |    |    | CEATAEND | SDIOIT | RXDAVL | TXDAVL | RXFIFOE | TXFIFOE | RXFIFO | TXFIFO | RXFIFOHF | TXFIFOHE | RXACT | TXACT | CMDACT | DBCKEND | STBITERR | DATAEND | CMDSENT | CMDREND | RXOVERR | TXUNDERR | DTIMEOUT | CTIMEOUT | DCRCFAIL | CCRCFAIL |
|          |    |    |    |    |    |    |    | r        | r      | r      | r      | r       | r       | r      | r      | r        | r        | r     | r     | r      | r       | r        | r       | r       | r       | r       | r        | r        | r        | r        | r        |

Bits 31:24 Reserved, must be kept at reset value

Bit 23 **CEATAEND**: CE-ATA command completion signal received for CMD61

Bit 22 **SDIOIT**: SDIO interrupt received

Bit 21 **RXDAVL**: Data available in receive FIFO

Bit 20 **TXDAVL**: Data available in transmit FIFO

Bit 19 **RXFIFOE**: Receive FIFO empty

Bit 18 **TXFIFOE**: Transmit FIFO empty

When HW Flow Control is enabled, TXFIFOE signals becomes activated when the FIFO contains 2 words.

Bit 17 **RXFIFO**: Receive FIFO full

When HW Flow Control is enabled, RXFIFO signals becomes activated 2 words before the FIFO is full.

Bit 16 **TXFIFO**: Transmit FIFO full

Bit 15 **RXFIFOHF**: Receive FIFO half full: there are at least 8 words in the FIFO

Bit 14 **TXFIFOHE**: Transmit FIFO half empty: at least 8 words can be written into the FIFO

Bit 13 **RXACT**: Data receive in progress

Bit 12 **TXACT**: Data transmit in progress

Bit 11 **CMDACT**: Command transfer in progress

Bit 10 **DBCKEND**: Data block sent/received (CRC check passed)

Bit 9 **STBITERR**: Start bit not detected on all data signals in wide bus mode

Bit 8 **DATAEND**: Data end (data counter, SDIDCOUNT, is zero)

Bit 7 **CMDSENT**: Command sent (no response required)

Bit 6 **CMDREND**: Command response received (CRC check passed)

Bit 5 **RXOVERR**: Received FIFO overrun error

Bit 4 **TXUNDERR**: Transmit FIFO underrun error

Bit 3 **DTIMEOUT**: Data timeout

Bit 2 **CTIMEOUT**: Command response timeout

The Command TimeOut period has a fixed value of 64 SDIO\_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)

### 31.9.12 SDIO interrupt clear register (SDIO\_ICR)

Address offset: 0x38

Reset value: 0x0000 0000

The SDIO\_ICR register is a write-only register. Writing a bit with 1b clears the corresponding bit in the SDIO\_STA Status register.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22      | 21       | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10       | 9         | 8        | 7        | 6       | 5        | 4         | 3         | 2         | 1         | 0         |
|----------|----|----|----|----|----|----|----|-----------|---------|----------|----|----|----|----|----|----|----|----|----|----|----------|-----------|----------|----------|---------|----------|-----------|-----------|-----------|-----------|-----------|
| Reserved |    |    |    |    |    |    |    | CEATAENDC | SDIOITC | Reserved |    |    |    |    |    |    |    |    |    |    | DBCKENDC | STBITERRC | DATAENDC | CMDSENTC | CMDREND | RXOVERRC | TXUNDERRC | DTIMEOUTC | CTIMEOUTC | DCRCFAILC | CCRCFAILC |
|          |    |    |    |    |    |    |    | r/w       | r/w     |          |    |    |    |    |    |    |    |    |    |    | r/w      | r/w       | r/w      | r/w      | r/w     | r/w      | r/w       | r/w       | r/w       | r/w       | r/w       |

Bits 31:24 Reserved, must be kept at reset value

Bit 23 **CEATAENDC**: CEATAEND flag clear bit

Set by software to clear the CEATAEND flag.

0: CEATAEND not cleared

1: CEATAEND cleared

Bit 22 **SDIOITC**: SDIOIT flag clear bit

Set by software to clear the SDIOIT flag.

0: SDIOIT not cleared

1: SDIOIT cleared

Bits 21:11 Reserved, must be kept at reset value

Bit 10 **DBCKENDC**: DBCKEND flag clear bit

Set by software to clear the DBCKEND flag.

0: DBCKEND not cleared

1: DBCKEND cleared

Bit 9 **STBITERRC**: STBITERR flag clear bit

Set by software to clear the STBITERR flag.

0: STBITERR not cleared

1: STBITERR cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit

Set by software to clear the DATAEND flag.

0: DATAEND not cleared

1: DATAEND cleared

- Bit 7 **CMDSENTC**: CMDSENT flag clear bit  
Set by software to clear the CMDSENT flag.  
0: CMDSENT not cleared  
1: CMDSENT cleared
- Bit 6 **CMDREND**C: CMDREND flag clear bit  
Set by software to clear the CMDREND flag.  
0: CMDREND not cleared  
1: CMDREND cleared
- Bit 5 **RXOVERRC**: RXOVERR flag clear bit  
Set by software to clear the RXOVERR flag.  
0: RXOVERR not cleared  
1: RXOVERR cleared
- Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit  
Set by software to clear TXUNDERR flag.  
0: TXUNDERR not cleared  
1: TXUNDERR cleared
- Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit  
Set by software to clear the DTIMEOUT flag.  
0: DTIMEOUT not cleared  
1: DTIMEOUT cleared
- Bit 2 **CTIMEOUTC**: CTIMEOUT flag clear bit  
Set by software to clear the CTIMEOUT flag.  
0: CTIMEOUT not cleared  
1: CTIMEOUT cleared
- Bit 1 **DCRCFAILC**: DCRCFAIL flag clear bit  
Set by software to clear the DCRCFAIL flag.  
0: DCRCFAIL not cleared  
1: DCRCFAIL cleared
- Bit 0 **CCRCFAILC**: CCRCFAIL flag clear bit  
Set by software to clear the CCRCFAIL flag.  
0: CCRCFAIL not cleared  
1: CCRCFAIL cleared

### 31.9.13 SDIO mask register (SDIO\_MASK)

Address offset: 0x3C

Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1b.

Bits 31:24 Reserved, must be kept at reset value

Bit 23 **CEATAENDIE**: CE-ATA command completion signal received interrupt enable

Set and cleared by software to enable/disable the interrupt generated when receiving the CE-ATA command completion signal.

0: CE-ATA command completion signal received interrupt disabled

1: CE-ATA command completion signal received interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable

Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.

0: SDIO Mode Interrupt Received interrupt disabled

1: SDIO Mode Interrupt Received interrupt enabled

Bit 21 **RXDAVLIE**: Data available in Rx FIFO interrupt enable

Set and cleared by software to enable/disable the interrupt generated by the presence of data available in Rx FIFO.

0: Data available in Rx FIFO interrupt disabled

1: Data available in Rx FIFO interrupt enabled

Bit 20 **TXDAVLIE**: Data available in Tx FIFO interrupt enable

Set and cleared by software to enable/disable the interrupt generated by the presence of data available in Tx FIFO.

0: Data available in Tx FIFO interrupt disabled

1: Data available in Tx FIFO interrupt enabled

Bit 19 **RXFIFOEIE**: Rx FIFO empty interrupt enable

Set and cleared by software to enable/disable interrupt caused by Rx FIFO empty.

0: Rx FIFO empty interrupt disabled

1: Rx FIFO empty interrupt enabled

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable

Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.

0: Tx FIFO empty interrupt disabled

1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOEIE**: Rx FIFO full interrupt enable

Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.

0: Rx FIFO full interrupt disabled

1: Rx FIFO full interrupt enabled

- Bit 16 **TXFIFOFIE**: Tx FIFO full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO full.  
0: Tx FIFO full interrupt disabled  
1: Tx FIFO full interrupt enabled
- Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.  
0: Rx FIFO half full interrupt disabled  
1: Rx FIFO half full interrupt enabled
- Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.  
0: Tx FIFO half empty interrupt disabled  
1: Tx FIFO half empty interrupt enabled
- Bit 13 **RXACTIE**: Data receive acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data being received (data receive acting).  
0: Data receive acting interrupt disabled  
1: Data receive acting interrupt enabled
- Bit 12 **TXACTIE**: Data transmit acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data being transferred (data transmit acting).  
0: Data transmit acting interrupt disabled  
1: Data transmit acting interrupt enabled
- Bit 11 **CMDACTIE**: Command acting interrupt enable  
Set and cleared by software to enable/disable interrupt caused by a command being transferred (command acting).  
0: Command acting interrupt disabled  
1: Command acting interrupt enabled
- Bit 10 **DBCKENDIE**: Data block end interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data block end.  
0: Data block end interrupt disabled  
1: Data block end interrupt enabled
- Bit 9 **STBITERRIE**: Start bit error interrupt enable  
Set and cleared by software to enable/disable interrupt caused by start bit error.  
0: Start bit error interrupt disabled  
1: Start bit error interrupt enabled
- Bit 8 **DATAENDIE**: Data end interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data end.  
0: Data end interrupt disabled  
1: Data end interrupt enabled
- Bit 7 **CMDSENTIE**: Command sent interrupt enable  
Set and cleared by software to enable/disable interrupt caused by sending command.  
0: Command sent interrupt disabled  
1: Command sent interrupt enabled

- Bit 6 **CMDRENDIE**: Command response received interrupt enable  
Set and cleared by software to enable/disable interrupt caused by receiving command response.  
0: Command response received interrupt disabled  
1: command Response Received interrupt enabled
- Bit 5 **RXOVERRIE**: Rx FIFO overrun error interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.  
0: Rx FIFO overrun error interrupt disabled  
1: Rx FIFO overrun error interrupt enabled
- Bit 4 **TXUNDERRIE**: Tx FIFO underrun error interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.  
0: Tx FIFO underrun error interrupt disabled  
1: Tx FIFO underrun error interrupt enabled
- Bit 3 **DTIMEOUTIE**: Data timeout interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data timeout.  
0: Data timeout interrupt disabled  
1: Data timeout interrupt enabled
- Bit 2 **CTIMEOUTIE**: Command timeout interrupt enable  
Set and cleared by software to enable/disable interrupt caused by command timeout.  
0: Command timeout interrupt disabled  
1: Command timeout interrupt enabled
- Bit 1 **DCRCFAILIE**: Data CRC fail interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data CRC failure.  
0: Data CRC fail interrupt disabled  
1: Data CRC fail interrupt enabled
- Bit 0 **CCRCFAILIE**: Command CRC fail interrupt enable  
Set and cleared by software to enable/disable interrupt caused by command CRC failure.  
0: Command CRC fail interrupt disabled  
1: Command CRC fail interrupt enabled

### 31.9.14 SDIO FIFO counter register (SDIO\_FIFOCNT)

Address offset: 0x48

Reset value: 0x0000 0000

The SDIO\_FIFOCNT register contains the remaining number of words to be written to or read from the FIFO. The FIFO counter loads the value from the data length register (see SDIO\_DLEN) when the data transfer enable bit, DTEN, is set in the data control register (SDIO\_DCTRL register) and the DPSM is at the Idle state. If the data length is not word-aligned (multiple of 4), the remaining 1 to 3 bytes are regarded as a word.

Bits 31:24 Reserved, must be kept at reset value

Bits 23:0 **FIFOCOUNT**: Remaining number of words to be written to or read from the FIFO.

### 31.9.15 SDIO data FIFO register (SDIO\_FIFO)

Address offset: 0x80

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This allows the CPU to use its load and store multiple operands to read from/write to the FIFO.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| FIFOData |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

bits 31:0 **FIFOData**: Receive and transmit FIFO data

The FIFO data occupies 32 entries of 32-bit words, from address:  
SDIO base + 0x080 to SDIO base + 0xFC.

### 31.9.16 SDIO register map

The following table summarizes the SDIO registers.

**Table 182. SDIO register map**

| Offset | Register     | 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17        | 16      | 15         | 14          | 13         | 12       | 11      | 10       | 9        | 8      | 7     | 6    | 5       | 4 | 3 | 2 | 1      | 0 |

## 32 Controller area network (bxCAN)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 32.1 bxCAN introduction

The **Basic Extended CAN** peripheral, named **bxCAN**, interfaces the CAN network. It supports the CAN protocols version 2.0A and B. It has been designed to manage a high number of incoming messages efficiently with a minimum CPU load. It also meets the priority requirements for transmit messages.

For safety-critical applications, the CAN controller provides all hardware functions for supporting the CAN Time Triggered Communication option.

### 32.2 bxCAN main features

- Supports CAN protocol version 2.0 A, B Active
- Bit rates up to 1 Mbit/s
- Supports the Time Triggered Communication option

#### Transmission

- Three transmit mailboxes
- Configurable transmit priority
- Time Stamp on SOF transmission

#### Reception

- Two receive FIFOs with three stages
- Scalable filter banks:
  - 28 filter banks shared between CAN1 and CAN2
- Identifier list feature
- Configurable FIFO overrun
- Time Stamp on SOF reception

#### Time-triggered communication option

- Disable automatic retransmission mode
- 16-bit free running timer
- Time Stamp sent in last two data bytes

#### Management

- Maskable interrupts
- Software-efficient mailbox mapping at a unique address space

### Dual CAN

- CAN1: Master bxCAN for managing the communication between a Slave bxCAN and the 512-byte SRAM memory
- CAN2: Slave bxCAN, with no direct access to the SRAM memory.
- The two bxCAN cells share the 512-byte SRAM memory (see [Figure 335](#))

## 32.3 bxCAN general description

In today's CAN applications, the number of nodes in a network is increasing and often several networks are linked together via gateways. Typically the number of messages in the system (and thus to be handled by each node) has significantly increased. In addition to the application messages, Network Management and Diagnostic messages have been introduced.

- An enhanced filtering mechanism is required to handle each type of message.

Furthermore, application tasks require more CPU time, therefore real-time constraints caused by message reception have to be reduced.

- A receive FIFO scheme allows the CPU to be dedicated to application tasks for a long time period without losing messages.

The standard HLP (Higher Layer Protocol) based on standard CAN drivers requires an efficient interface to the CAN controller.

**Figure 334. CAN network topology**

### 32.3.1 CAN 2.0B active core

The bxCAN module handles the transmission and the reception of CAN messages fully autonomously. Standard identifiers (11-bit) and extended identifiers (29-bit) are fully supported by hardware.

### 32.3.2 Control, status and configuration registers

The application uses these registers to:

- Configure CAN parameters, e.g. baud rate
- Request transmissions
- Handle receptions
- Manage interrupts
- Get diagnostic information

### 32.3.3 Tx mailboxes

Three transmit mailboxes are provided to the software for setting up messages. The transmission Scheduler decides which mailbox has to be transmitted first.

### 32.3.4 Acceptance filters

The bxCAN provides 28 scalable/configurable identifier filter banks for selecting the incoming messages the software needs and discarding the others.

#### Receive FIFO

Two receive FIFOs are used by hardware to store the incoming messages. Three complete messages can be stored in each FIFO. The FIFOs are managed completely by hardware.

Figure 335. Dual CAN block diagram

## 32.4 bxCAN operating modes

bxCAN has three main operating modes: **initialization**, **normal** and **Sleep**. After a hardware reset, bxCAN is in Sleep mode to reduce power consumption and an internal pull-up is active on CANTX. The software requests bxCAN to enter **initialization** or **Sleep** mode by setting the INRQ or SLEEP bits in the CAN\_MCR register. Once the mode has been entered, bxCAN confirms it by setting the INAK or SLAK bits in the CAN\_MSR register and the internal pull-up is disabled. When neither INAK nor SLAK are set, bxCAN is in **normal**

mode. Before entering **normal** mode bxCAN always has to **synchronize** on the CAN bus. To synchronize, bxCAN waits until the CAN bus is idle, this means 11 consecutive recessive bits have been monitored on CANRX.

### 32.4.1 Initialization mode

The software initialization can be done while the hardware is in Initialization mode. To enter this mode the software sets the INRQ bit in the CAN\_MCR register and waits until the hardware has confirmed the request by setting the INAK bit in the CAN\_MSR register.

To leave Initialization mode, the software clears the INRQ bit. bxCAN has left Initialization mode once the INAK bit has been cleared by hardware.

While in Initialization Mode, all message transfers to and from the CAN bus are stopped and the status of the CAN bus output CANTX is recessive (high).

Entering Initialization Mode does not change any of the configuration registers.

To initialize the CAN Controller, software has to set up the Bit Timing (CAN\_BTR) and CAN options (CAN\_MCR) registers.

To initialize the registers associated with the CAN filter banks (mode, scale, FIFO assignment, activation and filter values), software has to set the FINIT bit (CAN\_FMR). Filter initialization also can be done outside the initialization mode.

*Note:* When FINIT=1, CAN reception is deactivated.

*The filter values also can be modified by deactivating the associated filter activation bits (in the CAN\_FA1R register).*

*If a filter bank is not used, it is recommended to leave it non active (leave the corresponding FACT bit cleared).*

### 32.4.2 Normal mode

Once the initialization is complete, the software must request the hardware to enter Normal mode to be able to synchronize on the CAN bus and start reception and transmission.

The request to enter Normal mode is issued by clearing the INRQ bit in the CAN\_MCR register. The bxCAN enters Normal mode and is ready to take part in bus activities when it has synchronized with the data transfer on the CAN bus. This is done by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus Idle state). The switch to Normal mode is confirmed by the hardware by clearing the INAK bit in the CAN\_MSR register.

The initialization of the filter values is independent from Initialization Mode but must be done while the filter is not active (corresponding FACTx bit cleared). The filter scale and mode configuration must be configured before entering Normal Mode.

### 32.4.3 Sleep mode (low-power)

To reduce power consumption, bxCAN has a low-power mode called Sleep mode. This mode is entered on software request by setting the SLEEP bit in the CAN\_MCR register. In this mode, the bxCAN clock is stopped, however software can still access the bxCAN mailboxes.

If software requests entry to **initialization** mode by setting the INRQ bit while bxCAN is in **Sleep** mode, it must also clear the SLEEP bit.

bxCAN can be woken up (exit Sleep mode) either by software clearing the SLEEP bit or on detection of CAN bus activity.

On CAN bus activity detection, hardware automatically performs the wake-up sequence by clearing the SLEEP bit if the AWUM bit in the CAN\_MCR register is set. If the AWUM bit is cleared, software has to clear the SLEEP bit when a wake-up interrupt occurs, in order to exit from Sleep mode.

**Note:** *If the wake-up interrupt is enabled (WKUIE bit set in CAN\_IER register) a wake-up interrupt is generated on detection of CAN bus activity, even if the bxCAN automatically performs the wake-up sequence.*

After the SLEEP bit has been cleared, Sleep mode is exited once bxCAN has synchronized with the CAN bus, refer to [Figure 336](#). The Sleep mode is exited once the SLAK bit has been cleared by hardware.

**Figure 336. bxCAN operating modes**

1. ACK = The wait state during which hardware confirms a request by setting the INAK or SLAK bits in the CAN\_MSR register
2. SYNC = The state during which bxCAN waits until the CAN bus is idle, meaning 11 consecutive recessive bits have been monitored on CANRX

## 32.5 Test mode

Test mode can be selected by the SILM and LBKM bits in the CAN\_BTR register. These bits must be configured while bxCAN is in Initialization mode. Once test mode has been selected, the INRQ bit in the CAN\_MCR register must be reset to enter Normal mode.

### 32.5.1 Silent mode

The bxCAN can be put in Silent mode by setting the SILM bit in the CAN\_BTR register.

In Silent mode, the bxCAN is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and it cannot start a transmission. If the bxCAN has to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN Core monitors this dominant bit, although the CAN bus may

remain in recessive state. Silent mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames).

**Figure 337. bxCAN in silent mode**

### 32.5.2 Loop back mode

The bxCAN can be set in Loop Back Mode by setting the LBKM bit in the CAN\_BTR register. In Loop Back Mode, the bxCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) in a Receive mailbox.

**Figure 338. bxCAN in loop back mode**

This mode is provided for self-test functions. To be independent of external events, the CAN Core ignores acknowledge errors (no dominant bit sampled in the acknowledge slot of a data / remote frame) in Loop Back Mode. In this mode, the bxCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CANRX input pin is disregarded by the bxCAN. The transmitted messages can be monitored on the CANTX pin.

### 32.5.3 Loop back combined with silent mode

It is also possible to combine Loop Back mode and Silent mode by setting the LBKM and SILM bits in the CAN\_BTR register. This mode can be used for a “Hot Selftest”, meaning the bxCAN can be tested like in Loop Back mode but without affecting a running CAN system connected to the CANTX and CANRX pins. In this mode, the CANRX pin is disconnected from the bxCAN and the CANTX pin is held recessive.

Figure 339. bxCAN in combined mode

## 32.6 Debug mode

When the microcontroller enters the debug mode (Cortex<sup>®</sup>-M4 with FPU core halted), the bxCAN continues to work normally or stops, depending on:

- the DBG\_CAN1\_STOP bit for CAN1 or the DBG\_CAN2\_STOP bit for CAN2 in the DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).
- the DBF bit in CAN\_MCR. For more details, refer to [Section 32.9.2](#).

## 32.7 bxCAN functional description

### 32.7.1 Transmission handling

In order to transmit a message, the application must select one **empty** transmit mailbox, set up the identifier, the data length code (DLC) and the data before requesting the transmission by setting the corresponding TXRQ bit in the CAN\_TlRxR register. Once the mailbox has left **empty** state, the software no longer has write access to the mailbox registers. Immediately after the TXRQ bit has been set, the mailbox enters **pending** state and waits to become the highest priority mailbox, see *Transmit Priority*. As soon as the mailbox has the highest priority it is **scheduled** for transmission. The transmission of the message of the scheduled mailbox starts (enters **transmit** state) when the CAN bus becomes idle. Once the mailbox has been successfully transmitted, it becomes **empty** again. The hardware indicates a successful transmission by setting the RQCP and TXOK bits in the CAN\_TSR register.

If the transmission fails, the cause is indicated by the ALST bit in the CAN\_TSR register in case of an Arbitration Lost, and/or the TERR bit, in case of transmission error detection.

### Transmit priority

- By identifier When more than one transmit mailbox is pending, the transmission order is given by the identifier of the message stored in the mailbox. The message with the lowest identifier value has the highest priority according to the arbitration of the CAN protocol. If the identifier values are equal, the lower mailbox number is scheduled first.
- By transmit request order The transmit mailboxes can be configured as a transmit FIFO by setting the TXFP bit in the CAN\_MCR register. In this mode the priority order is given by the transmit request order. This mode is very useful for segmented transmission.

### Abort

A transmission request can be aborted by the user setting the ABRQ bit in the CAN\_TSR register. In **pending** or **scheduled** state, the mailbox is aborted immediately. An abort request while the mailbox is in **transmit** state can have two results. If the mailbox is transmitted successfully the mailbox becomes **empty** with the TXOK bit set in the CAN\_TSR register. If the transmission fails, the mailbox becomes **scheduled**, the transmission is aborted and becomes **empty** with TXOK cleared. In all cases the mailbox becomes **empty** again at least at the end of the current transmission.

### Nonautomatic retransmission mode

This mode has been implemented in order to fulfil the requirement of the Time Triggered Communication option of the CAN standard. To configure the hardware in this mode the NART bit in the CAN\_MCR register must be set.

In this mode, each transmission is started only once. If the first attempt fails, due to an arbitration loss or an error, the hardware does not automatically restart the message transmission.

At the end of the first transmission attempt, the hardware considers the request as completed and sets the RQCP bit in the CAN\_TSR register. The result of the transmission is indicated in the CAN\_TSR register by the TXOK, ALST and TERR bits.

Figure 340. Transmit mailbox states

### 32.7.2 Time triggered communication mode

In this mode, the internal counter of the CAN hardware is activated and used to generate the Time Stamp value stored in the CAN\_RDTxR/CAN\_TDTxR registers, respectively (for Rx and Tx mailboxes). The internal counter is incremented each CAN bit time (refer to [Section 32.7.7](#)). The internal counter is captured on the sample point of the Start Of Frame bit in both reception and transmission.

### 32.7.3 Reception handling

For the reception of CAN messages, three mailboxes organized as a FIFO are provided. In order to save CPU load, simplify the software and guarantee data consistency, the FIFO is managed completely by hardware. The application accesses the messages stored in the FIFO through the FIFO output mailbox.

#### Valid message

A received message is considered as valid **when** it has been received correctly according to the CAN protocol (no error until the last but one bit of the EOF field) **and** It passed through the identifier filtering successfully, see [Section 32.7.4](#).

Figure 341. Receive FIFO states

### FIFO management

Starting from the **empty** state, the first valid message received is stored in the FIFO which becomes **pending\_1**. The hardware signals the event setting the FMP[1:0] bits in the CAN\_RFR register to the value 01b. The message is available in the FIFO output mailbox. The software reads out the mailbox content and releases it by setting the RFOM bit in the CAN\_RFR register. The FIFO becomes **empty** again. If a new valid message has been received in the meantime, the FIFO stays in **pending\_1** state and the new message is available in the output mailbox.

If the application does not release the mailbox, the next valid message is stored in the FIFO which enters **pending\_2** state (FMP[1:0] = 10b). The storage process is repeated for the next valid message putting the FIFO into **pending\_3** state (FMP[1:0] = 11b). At this point, the software must release the output mailbox by setting the RFOM bit, so that a mailbox is free to store the next valid message. Otherwise the next valid message received causes a loss of message.

Refer also to [Section 32.7.5](#)

### Overrun

Once the FIFO is in **pending\_3** state (i.e. the three mailboxes are full) the next valid message reception leads to an **overrun** and a message is lost. The hardware signals the

overrun condition by setting the FOVR bit in the CAN\_RFR register. Which message is lost depends on the configuration of the FIFO:

- If the FIFO lock function is disabled (RFLM bit in the CAN\_MCR register cleared) the last message stored in the FIFO is overwritten by the new incoming message. In this case the latest messages are always available to the application.
- If the FIFO lock function is enabled (RFLM bit in the CAN\_MCR register set) the most recent message is discarded and the software has the three oldest messages in the FIFO available.

### Reception related interrupts

Once a message has been stored in the FIFO, the FMP[1:0] bits are updated and an interrupt request is generated if the FMPIE bit in the CAN\_IER register is set.

When the FIFO becomes full (i.e. a third message is stored) the FULL bit in the CAN\_RFR register is set and an interrupt is generated if the FFIE bit in the CAN\_IER register is set.

On overrun condition, the FOVR bit is set and an interrupt is generated if the FOVIE bit in the CAN\_IER register is set.

## 32.7.4 Identifier filtering

In the CAN protocol the identifier of a message is not associated with the address of a node but related to the content of the message. Consequently a transmitter broadcasts its message to all receivers. On message reception a receiver node decides - depending on the identifier value - whether the software needs the message or not. If the message is needed, it is copied into the SRAM. If not, the message must be discarded without intervention by the software.

To fulfill this requirement, the bxCAN Controller provides 28 configurable and scalable filter banks (27-0) to the application. This hardware filtering saves CPU resources which would be otherwise needed to perform filtering by software. Each filter bank *x* consists of two 32-bit registers, CAN\_FxR0 and CAN\_FxR1.

### Scalable width

To optimize and adapt the filters to the application needs, each filter bank can be scaled independently. Depending on the filter scale a filter bank provides:

- One 32-bit filter for the STDID[10:0], EXTID[17:0], IDE and RTR bits.
- Two 16-bit filters for the STDID[10:0], RTR, IDE and EXTID[17:15] bits.

Refer to [Figure 342](#).

Furthermore, the filters can be configured in mask mode or in identifier list mode.

### Mask mode

In **mask** mode the identifier registers are associated with mask registers specifying which bits of the identifier are handled as “must match” or as “don’t care”.

### Identifier list mode

In **identifier list** mode, the mask registers are used as identifier registers. Thus instead of defining an identifier and a mask, two identifiers are specified, doubling the number of single identifiers. All bits of the incoming identifier must match the bits specified in the filter registers.

## Filter bank scale and mode configuration

The filter banks are configured by means of the corresponding CAN\_FMR register. To configure a filter bank it must be deactivated by clearing the FACT bit in the CAN\_FAR register. The filter scale is configured by means of the corresponding FSCx bit in the CAN\_FS1R register, refer to [Figure 342](#). The **identifier list** or **identifier mask** mode for the corresponding Mask/Identifier registers is configured by means of the FBMx bits in the CAN\_FMR register.

To filter a group of identifiers, configure the Mask/Identifier registers in mask mode.

To select single identifiers, configure the Mask/Identifier registers in identifier list mode.

Filters not used by the application should be left deactivated.

Each filter within a filter bank is numbered (called the *Filter Number*) from 0 to a maximum dependent on the mode and the scale of each of the filter banks.

Concerning the filter configuration, refer to [Figure 342](#).

**Figure 342. Filter bank scale configuration - register organization**

## Filter match index

Once a message has been received in the FIFO it is available to the application. Typically, application data is copied into SRAM locations. To copy the data to the right location the

application has to identify the data by means of the identifier. To avoid this, and to ease the access to the SRAM locations, the CAN controller provides a Filter Match Index.

This index is stored in the mailbox together with the message according to the filter priority rules. Thus each received message has its associated filter match index.

The Filter Match index can be used in two ways:

- Compare the Filter Match index with a list of expected values.
- Use the Filter Match Index as an index on an array to access the data destination location.

For nonmasked filters, the software no longer has to compare the identifier.

If the filter is masked the software reduces the comparison to the masked bits only.

The index value of the filter number does not take into account the activation state of the filter banks. In addition, two independent numbering schemes are used, one for each FIFO. Refer to [Figure 343](#) for an example.

**Figure 343. Example of filter numbering**

| Filter Bank | FIFO0                        | Filter Num.      | Filter Bank | FIFO1                        | Filter Num.        |
|-------------|------------------------------|------------------|-------------|------------------------------|--------------------|
| 0           | ID List (32-bit)             | 0<br>1           | 2           | ID Mask (16-bit)             | 0<br>1             |
| 1           | ID Mask (32-bit)             | 2                | 4           | ID List (32-bit)             | 2<br>3             |
| 3           | ID List (16-bit)             | 3<br>4<br>5<br>6 | 7           | Deactivated ID Mask (16-bit) | 4<br>5             |
| 5           | Deactivated ID List (32-bit) | 7<br>8           | 8           | ID Mask (16-bit)             | 6<br>7             |
| 6           | ID Mask (16-bit)             | 9<br>10          | 10          | Deactivated ID List (16-bit) | 8<br>9<br>10<br>11 |
| 9           | ID List (32-bit)             | 11<br>12         | 11          | ID List (32-bit)             | 12<br>13           |
| 13          | ID Mask (32-bit)             | 13               | 12          | ID Mask (32-bit)             | 14                 |

ID = Identifier

### Filter priority rules

Depending on the filter combination it may occur that an identifier passes successfully through several filters. In this case the filter match value stored in the receive mailbox is chosen according to the following priority rules:

- A 32-bit filter takes priority over a 16-bit filter.
- For filters of equal scale, priority is given to the Identifier List mode over the Identifier Mask mode
- For filters of equal scale and mode, priority is given by the filter number (the lower the number, the higher the priority).

**Figure 344. Filtering mechanism - Example**

The example above shows the filtering principle of the bxCAN. On reception of a message, the identifier is compared first with the filters configured in identifier list mode. If there is a match, the message is stored in the associated FIFO and the index of the matching filter is stored in the Filter Match Index. As shown in the example, the identifier matches with Identifier #2 thus the message content and FMI 2 is stored in the FIFO.

If there is no match, the incoming identifier is then compared with the filters configured in mask mode.

If the identifier does not match any of the identifiers configured in the filters, the message is discarded by hardware without disturbing the software.

### 32.7.5 Message storage

The interface between the software and the hardware for the CAN messages is implemented by means of mailboxes. A mailbox contains all information related to a message; identifier, data, control, status and time stamp information.

#### Transmit mailbox

The software sets up the message to be transmitted in an empty transmit mailbox. The status of the transmission is indicated by hardware in the CAN\_TSR register.

**Table 183. Transmit mailbox mapping**

| Offset to transmit mailbox base address (bytes) | Register name |
|-------------------------------------------------|---------------|
| 0                                               | CAN_TlRxR     |
| 4                                               | CAN_TDTxR     |
| 8                                               | CAN_TDLxR     |
| 12                                              | CAN_TDHxR     |

#### Receive mailbox

When a message has been received, it is available to the software in the FIFO output mailbox. Once the software has handled the message (e.g. read it) the software must release the FIFO output mailbox by means of the RFOM bit in the CAN\_RFR register to make the next incoming message available. The filter match index is stored in the MFMI field of the CAN\_RDTxR register. The 16-bit time stamp value is stored in the TIME[15:0] field of CAN\_RDTxR.

**Table 184. Receive mailbox mapping**

| Offset to receive mailbox base address (bytes) | Register name |
|------------------------------------------------|---------------|
| 0                                              | CAN_RlRxR     |
| 4                                              | CAN_RDTxR     |
| 8                                              | CAN_RDLxR     |
| 12                                             | CAN_RDHxR     |

Figure 345. CAN error state diagram

### 32.7.6 Error management

The error management as described in the CAN protocol is handled entirely by hardware using a Transmit Error Counter (TEC value, in CAN\_ESR register) and a Receive Error Counter (REC value, in the CAN\_ESR register), which get incremented or decremented according to the error condition. For detailed information about TEC and REC management, refer to the CAN standard.

Both of them may be read by software to determine the stability of the network. Furthermore, the CAN hardware provides detailed information on the current error status in CAN\_ESR register. By means of the CAN\_IER register (ERRIE bit, etc.), the software can configure the interrupt generation on error detection in a very flexible way.

#### Bus-Off recovery

The Bus-Off state is reached when TEC is greater than 255, this state is indicated by BOFF bit in CAN\_ESR register. In Bus-Off state, the bxCAN is no longer able to transmit and receive messages.

Depending on the ABOM bit in the CAN\_MCR register bxCAN recovers from Bus-Off (become error active again) either automatically or on software request. But in both cases the bxCAN has to wait at least for the recovery sequence specified in the CAN standard (128 occurrences of 11 consecutive recessive bits monitored on CANRX).

If ABOM is set, the bxCAN starts the recovering sequence automatically after it has entered Bus-Off state.

If ABOM is cleared, the software must initiate the recovering sequence by requesting bxCAN to enter and to leave initialization mode.

*Note:* In initialization mode, bxCAN does not monitor the CANRX signal, therefore it cannot complete the recovery sequence. **To recover, bxCAN must be in normal mode.**

### 32.7.7 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

Its operation may be explained simply by splitting nominal bit time into three segments as follows:

- **Synchronization segment (SYNC\_SEG):** a bit change is expected to occur within this time segment. It has a fixed length of one time quantum ( $1 \times t_q$ ).
- **Bit segment 1 (BS1):** defines the location of the sample point. It includes the PROP\_SEG and PHASE\_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.
- **Bit segment 2 (BS2):** defines the location of the transmit point. It represents the PHASE\_SEG2 of the CAN standard. Its duration is programmable between 1 and 8 time quanta but may also be automatically shortened to compensate for negative phase drifts.

The resynchronization Jump Width (SJW) defines an upper bound to the amount of lengthening or shortening of the bit segments. It is programmable between 1 and 4 time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC\_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC\_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the Bit Timing register (CAN\_BTR) is only possible while the device is in Standby mode.

**Note:** For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898 standard.

**Figure 346. Bit timing**

Figure 347. CAN frames

## 32.8 bxCAN interrupts

Four interrupt vectors are dedicated to bxCAN. Each interrupt source can be independently enabled or disabled by means of the CAN Interrupt Enable register (CAN\_IER).

Figure 348. Event flags and interrupt generation

- The **transmit interrupt** can be generated by the following events:
  - Transmit mailbox 0 becomes empty, RQCP0 bit in the CAN\_TSR register set.
  - Transmit mailbox 1 becomes empty, RQCP1 bit in the CAN\_TSR register set.
  - Transmit mailbox 2 becomes empty, RQCP2 bit in the CAN\_TSR register set.
- The **FIFO 0 interrupt** can be generated by the following events:
  - Reception of a new message, FMP0 bits in the CAN\_RF0R register are not '00'.
  - FIFO0 full condition, FULL0 bit in the CAN\_RF0R register set.
  - FIFO0 overrun condition, FOVR0 bit in the CAN\_RF0R register set.
- The **FIFO 1 interrupt** can be generated by the following events:
  - Reception of a new message, FMP1 bits in the CAN\_RF1R register are not '00'.
  - FIFO1 full condition, FULL1 bit in the CAN\_RF1R register set.
  - FIFO1 overrun condition, FOVR1 bit in the CAN\_RF1R register set.
- The **error and status change interrupt** can be generated by the following events:
  - Error condition, for more details on error conditions refer to the CAN Error Status register (CAN\_ESR).

- Wake-up condition, SOF monitored on the CAN Rx signal.
- Entry into Sleep mode.

## 32.9 CAN registers

The peripheral registers have to be accessed by words (32 bits).

### 32.9.1 Register access protection

Erroneous access to certain configuration registers can cause the hardware to temporarily disturb the whole CAN network. Therefore the CAN\_BTR register can be modified by software only while the CAN hardware is in initialization mode.

Although the transmission of incorrect data does not cause problems at the CAN network level, it can severely disturb the application. A transmit mailbox can be only modified by software while it is in empty state, refer to [Figure 340](#).

The filter values can be modified either deactivating the associated filter banks or by setting the FINIT bit. Moreover, the modification of the filter configuration (scale, mode and FIFO assignment) in CAN\_FMR, CAN\_FSR and CAN\_FFR registers can only be done when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

### 32.9.2 CAN control and status registers

Refer to [Section 2.2 on page 45](#) for a list of abbreviations used in register descriptions.

#### CAN master control register (CAN\_MCR)

Address offset: 0x00

Reset value: 0x0001 0002

|          |          |    |    |    |    |    |    |      |      |      |      |      |      |       |      |
|----------|----------|----|----|----|----|----|----|------|------|------|------|------|------|-------|------|
| 31       | 30       | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21   | 20   | 19   | 18   | 17    | 16   |
| Reserved |          |    |    |    |    |    |    |      |      |      |      |      |      |       | DBF  |
|          |          |    |    |    |    |    |    |      |      |      |      |      |      |       | rw   |
| 15       | 14       | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6    | 5    | 4    | 3    | 2    | 1     | 0    |
| RESET    | Reserved |    |    |    |    |    |    | TTCM | ABOM | AWUM | NART | RFLM | TXFP | SLEEP | INRQ |
| rs       |          |    |    |    |    |    |    | rw   | rw   | rw   | rw   | rw   | rw   | rw    | rw   |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DBF**: Debug freeze

0: CAN working during debug

1: CAN reception/transmission frozen during debug. Reception FIFOs can still be accessed/controlled normally.

Bit 15 **RESET**: bxCAN software master reset

0: Normal operation.

1: Force a master reset of the bxCAN -> Sleep mode activated after reset (FMP bits and CAN\_MCR register are initialized to the reset values). This bit is automatically reset to 0.

Bits 14:8 Reserved, must be kept at reset value.

**Bit 7 TTCM:** Time triggered communication mode

- 0: Time Triggered Communication mode disabled.
- 1: Time Triggered Communication mode enabled

*Note:* For more information on Time Triggered Communication mode refer to [Section 32.7.2](#).

**Bit 6 ABOM:** Automatic bus-off management

This bit controls the behavior of the CAN hardware on leaving the Bus-Off state.

- 0: The Bus-Off state is left on software request, once 128 occurrences of 11 recessive bits have been monitored and the software has first set and cleared the INRQ bit of the CAN\_MCR register.

- 1: The Bus-Off state is left automatically by hardware once 128 occurrences of 11 recessive bits have been monitored.

For detailed information on the Bus-Off state refer to [Section 32.7.6](#).

**Bit 5 AWUM:** Automatic wake-up mode

This bit controls the behavior of the CAN hardware on message reception during Sleep mode.

- 0: The Sleep mode is left on software request by clearing the SLEEP bit of the CAN\_MCR register.

- 1: The Sleep mode is left automatically by hardware on CAN message detection.

The SLEEP bit of the CAN\_MCR register and the SLAK bit of the CAN\_MSR register are cleared by hardware.

**Bit 4 NART:** No automatic retransmission

- 0: The CAN hardware automatically retransmits the message until it has been successfully transmitted according to the CAN standard.

- 1: A message is transmitted only once, independently of the transmission result (successful, error or arbitration lost).

**Bit 3 RFLM:** Receive FIFO locked mode

- 0: Receive FIFO not locked on overrun. Once a receive FIFO is full the next incoming message overwrites the previous one.

- 1: Receive FIFO locked against overrun. Once a receive FIFO is full the next incoming message is discarded.

**Bit 2 TXFP:** Transmit FIFO priority

This bit controls the transmission order when several mailboxes are pending at the same time.

- 0: Priority driven by the identifier of the message

- 1: Priority driven by the request order (chronologically)

**Bit 1 SLEEP:** Sleep mode request

This bit is set by software to request the CAN hardware to enter the Sleep mode. Sleep mode is entered as soon as the current CAN activity (transmission or reception of a CAN frame) has been completed.

This bit is cleared by software to exit Sleep mode.

This bit is cleared by hardware when the AWUM bit is set and a SOF bit is detected on the CAN Rx signal.

This bit is set after reset - CAN starts in Sleep mode.

**Bit 0 INRQ:** Initialization request

The software clears this bit to switch the hardware into normal mode. Once 11 consecutive recessive bits have been monitored on the Rx signal the CAN hardware is synchronized and ready for transmission and reception. Hardware signals this event by clearing the INAK bit in the CAN\_MSR register.

Software sets this bit to request the CAN hardware to enter initialization mode. Once software has set the INRQ bit, the CAN hardware waits until the current CAN activity (transmission or reception) is completed before entering the initialization mode. Hardware signals this event by setting the INAK bit in the CAN\_MSR register.

**CAN master status register (CAN\_MSR)**

Address offset: 0x04

Reset value: 0x0000 0C02

|           |    |    |    |    |      |     |     |          |    |    |    |       |       |       |      |      |

|           |    |    |    | r  | r    | r   | r   |          |    |    |    | rc_w1 | rc_w1 | rc_w1 | r    | r    |

Bits 31:12 Reserved, must be kept at reset value.

**Bit 11 RX:** CAN Rx signal

Monitors the actual value of the **CAN\_RX** Pin.

**Bit 10 SAMP:** Last sample point

The value of RX on the last sample point (current received bit value).

**Bit 9 RXM:** Receive mode

The CAN hardware is currently receiver.

**Bit 8 TXM:** Transmit mode

The CAN hardware is currently transmitter.

Bits 7:5 Reserved, must be kept at reset value.

**Bit 4 SLAKI:** Sleep acknowledge interrupt

When SLKIE=1, this bit is set by hardware to signal that the bxCAN has entered Sleep Mode. When set, this bit generates a status change interrupt if the SLKIE bit in the CAN\_IER register is set.

This bit is cleared by software or by hardware, when SLAK is cleared.

*Note: When SLKIE=0, no polling on SLAKI is possible. In this case the SLAK bit can be polled.*

**Bit 3 WKUI:** Wake-up interrupt

This bit is set by hardware to signal that a SOF bit has been detected while the CAN hardware was in Sleep mode. Setting this bit generates a status change interrupt if the WKUIE bit in the CAN\_IER register is set.

This bit is cleared by software.

**Bit 2 ERRI:** Error interrupt

This bit is set by hardware when a bit of the CAN\_ESR has been set on error detection and the corresponding interrupt in the CAN\_IER is enabled. Setting this bit generates a status change interrupt if the ERRIE bit in the CAN\_IER register is set.

This bit is cleared by software.

**Bit 1 SLAK:** Sleep acknowledge

This bit is set by hardware and indicates to the software that the CAN hardware is now in Sleep mode. This bit acknowledges the Sleep mode request from the software (set SLEEP bit in CAN\_MCR register).

This bit is cleared by hardware when the CAN hardware has left Sleep mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

*Note: The process of leaving Sleep mode is triggered when the SLEEP bit in the CAN\_MCR register is cleared. Refer to the AWUM bit of the CAN\_MCR register description for detailed information for clearing SLEEP bit*

**Bit 0 INAK:** Initialization acknowledge

This bit is set by hardware and indicates to the software that the CAN hardware is now in initialization mode. This bit acknowledges the initialization request from the software (set INRQ bit in CAN\_MCR register).

This bit is cleared by hardware when the CAN hardware has left the initialization mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

**CAN transmit status register (CAN\_TSR)**

Address offset: 0x08

Reset value: 0x1C00 0000

| 31    | 30               | 29   | 28   | 27    | 26    | 25        | 24    | 23    | 22       | 21 | 20 | 19    | 18    | 17    | 16    |

**Bit 31 LOW2:** Lowest priority flag for mailbox 2

This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 2 has the lowest priority.

**Bit 30 LOW1:** Lowest priority flag for mailbox 1

This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 1 has the lowest priority.

**Bit 29 LOW0:** Lowest priority flag for mailbox 0

This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 0 has the lowest priority.

*Note: The LOW[2:0] bits are set to zero when only one mailbox is pending.*

**Bit 28 TME2:** Transmit mailbox 2 empty

This bit is set by hardware when no transmit request is pending for mailbox 2.

**Bit 27 TME1:** Transmit mailbox 1 empty

This bit is set by hardware when no transmit request is pending for mailbox 1.

- Bit 26 **TME0**: Transmit mailbox 0 empty  
This bit is set by hardware when no transmit request is pending for mailbox 0.
- Bits 25:24 **CODE[1:0]**: Mailbox code  
In case at least one transmit mailbox is free, the code value is equal to the number of the next transmit mailbox free.  
In case all transmit mailboxes are pending, the code value is equal to the number of the transmit mailbox with the lowest priority.
- Bit 23 **ABRQ2**: Abort request for mailbox 2  
Set by software to abort the transmission request for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.  
Setting this bit has no effect when the mailbox is not pending for transmission.
- Bits 22:20 Reserved, must be kept at reset value.
- Bit 19 **TERR2**: Transmission error of mailbox 2  
This bit is set when the previous TX failed due to an error.
- Bit 18 **ALST2**: Arbitration lost for mailbox 2  
This bit is set when the previous TX failed due to an arbitration lost.
- Bit 17 **TXOK2**: Transmission OK of mailbox 2  
The hardware updates this bit after each transmission attempt.  
0: The previous transmission failed  
1: The previous transmission was successful  
This bit is set by hardware when the transmission request on mailbox 2 has been completed successfully. Refer to [Figure 340](#).
- Bit 16 **RQCP2**: Request completed mailbox2  
Set by hardware when the last request (transmit or abort) has been performed.  
Cleared by software writing a "1" or by hardware on transmission request (TXRQ2 set in CAN\_TMD2R register).  
Clearing this bit clears all the status bits (TXOK2, ALST2 and TERR2) for Mailbox 2.
- Bit 15 **ABRQ1**: Abort request for mailbox 1  
Set by software to abort the transmission request for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.  
Setting this bit has no effect when the mailbox is not pending for transmission.
- Bits 14:12 Reserved, must be kept at reset value.
- Bit 11 **TERR1**: Transmission error of mailbox1  
This bit is set when the previous TX failed due to an error.
- Bit 10 **ALST1**: Arbitration lost for mailbox1  
This bit is set when the previous TX failed due to an arbitration lost.
- Bit 9 **TXOK1**: Transmission OK of mailbox1  
The hardware updates this bit after each transmission attempt.  
0: The previous transmission failed  
1: The previous transmission was successful  
This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to [Figure 340](#).
- Bit 8 **RQCP1**: Request completed mailbox1  
Set by hardware when the last request (transmit or abort) has been performed.  
Cleared by software writing a "1" or by hardware on transmission request (TXRQ1 set in CAN\_TI1R register).  
Clearing this bit clears all the status bits (TXOK1, ALST1 and TERR1) for Mailbox 1.

Bit 7 **ABRQ0**: Abort request for mailbox0

Set by software to abort the transmission request for the corresponding mailbox.

Cleared by hardware when the mailbox becomes empty.

Setting this bit has no effect when the mailbox is not pending for transmission.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **TERR0**: Transmission error of mailbox0

This bit is set when the previous TX failed due to an error.

Bit 2 **ALST0**: Arbitration lost for mailbox0

This bit is set when the previous TX failed due to an arbitration lost.

Bit 1 **TXOK0**: Transmission OK of mailbox0

The hardware updates this bit after each transmission attempt.

0: The previous transmission failed

1: The previous transmission was successful

This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to [Figure 340](#)

Bit 0 **RQCP0**: Request completed mailbox0

Set by hardware when the last request (transmit or abort) has been performed.

Cleared by software writing a “1” or by hardware on transmission request (TXRQ0 set in CAN\_TIOR register).

Clearing this bit clears all the status bits (TXOK0, ALST0 and TERR0) for Mailbox 0.

### CAN receive FIFO 0 register (CAN\_RF0R)

Address offset: 0x0C

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |       |       |       |      |           |    |
|----------|----|----|----|----|----|----|----|----|----|-------|-------|-------|------|-----------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21    | 20    | 19    | 18   | 17        | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |       |       |       |      |           |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5     | 4     | 3     | 2    | 1         | 0  |
| Reserved |    |    |    |    |    |    |    |    |    | RFOM0 | FOVR0 | FULL0 | Res. | FMP0[1:0] |    |
|          |    |    |    |    |    |    |    |    |    | rs    | rc_w1 | rc_w1 |      | r         | r  |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RFOM0**: Release FIFO 0 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR0**: FIFO 0 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3 **FULL0**: FIFO 0 full

Set by hardware when three messages are stored in the FIFO.

This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP0[1:0]**: FIFO 0 message pending

These bits indicate how many messages are pending in the receive FIFO.

FMP is increased each time the hardware stores a new message in to the FIFO. FMP is decreased each time the software releases the output mailbox by setting the RFOM0 bit.

### CAN receive FIFO 1 register (CAN\_RF1R)

Address offset: 0x10

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |       |       |       |      |           |    |
|----------|----|----|----|----|----|----|----|----|----|-------|-------|-------|------|-----------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21    | 20    | 19    | 18   | 17        | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |       |       |       |      |           |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5     | 4     | 3     | 2    | 1         | 0  |
| Reserved |    |    |    |    |    |    |    |    |    | RFOM1 | FOVR1 | FULL1 | Res. | FMP1[1:0] |    |
|          |    |    |    |    |    |    |    |    |    | rs    | rc_w1 | rc_w1 |      | r         | r  |

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **RFOM1**: Release FIFO 1 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR1**: FIFO 1 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3 **FULL1**: FIFO 1 full

Set by hardware when three messages are stored in the FIFO.

This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP1[1:0]**: FIFO 1 message pending

These bits indicate how many messages are pending in the receive FIFO1.

FMP1 is increased each time the hardware stores a new message in to the FIFO1. FMP is decreased each time the software releases the output mailbox by setting the RFOM1 bit.

### CAN interrupt enable register (CAN\_IER)

Address offset: 0x14

Reset value: 0x0000 0000

|          |          |    |    |    |        |        |        |        |      |         |        |         |         |        |         |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SLKIE**: Sleep interrupt enable

- 0: No interrupt when SLAKI bit is set.
- 1: Interrupt generated when SLAKI bit is set.

Bit 16 **WKUIE**: Wake-up interrupt enable

- 0: No interrupt when WKUI is set.
- 1: Interrupt generated when WKUI bit is set.

Bit 15 **ERRIE**: Error interrupt enable

- 0: No interrupt is generated when an error condition is pending in the CAN\_ESR.
- 1: An interrupt is generation when an error condition is pending in the CAN\_ESR.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **LECIE**: Last error code interrupt enable

- 0: ERRI bit is not set when the error code in LEC[2:0] is set by hardware on error detection.
- 1: ERRI bit is set when the error code in LEC[2:0] is set by hardware on error detection.

Bit 10 **BOFIE**: Bus-off interrupt enable

- 0: ERRI bit is not set when BOFF is set.
- 1: ERRI bit is set when BOFF is set.

Bit 9 **EPVIE**: Error passive interrupt enable

- 0: ERRI bit is not set when EPVF is set.
- 1: ERRI bit is set when EPVF is set.

Bit 8 **EWGIE**: Error warning interrupt enable

- 0: ERRI bit is not set when EWGF is set.
- 1: ERRI bit is set when EWGF is set.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FOVIE1**: FIFO overrun interrupt enable

- 0: No interrupt when FOVR is set.
- 1: Interrupt generation when FOVR is set.

Bit 5 **FFIE1**: FIFO full interrupt enable

- 0: No interrupt when FULL bit is set.
- 1: Interrupt generated when FULL bit is set.

Bit 4 **FMP1E1**: FIFO message pending interrupt enable

- 0: No interrupt generated when state of FMP[1:0] bits are not 00b.
- 1: Interrupt generated when state of FMP[1:0] bits are not 00b.

Bit 3 **FOVIE0**: FIFO overrun interrupt enable

- 0: No interrupt when FOVR bit is set.
- 1: Interrupt generated when FOVR bit is set.

Bit 2 **FFIE0**: FIFO full interrupt enable

0: No interrupt when FULL bit is set.

1: Interrupt generated when FULL bit is set.

Bit 1 **FMPIE0**: FIFO message pending interrupt enable

0: No interrupt generated when state of FMP[1:0] bits are not 00b.

1: Interrupt generated when state of FMP[1:0] bits are not 00b.

Bit 0 **TMEIE**: Transmit mailbox empty interrupt enable

0: No interrupt when RQCPx bit is set.

1: Interrupt generated when RQCPx bit is set.

Note: Refer to [Section 32.8: bxCAN interrupts](#).

## CAN error status register (CAN\_ESR)

Address offset: 0x18

Reset value: 0x0000 0000

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20   | 19   | 18   | 17   | 16 |
|----------|----|----|----|----|----|----|----|----------|----|----|------|------|------|------|----|
| REC[7:0] |    |    |    |    |    |    |    | TEC[7:0] |    |    |      |      |      |      |    |
| r        | r  | r  | r  | r  | r  | r  | r  | r        | r  | r  | r    | r    | r    | r    | r  |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4    | 3    | 2    | 1    | 0  |
| Reserved |    |    |    |    |    |    |    | LEC[2:0] |    |    | Res. | BOFF | EPVF | EWGF |    |
|          |    |    |    |    |    |    |    | rw       | rw | rw |      | r    | r    | r    |    |

Bits 31:24 **REC[7:0]**: Receive error counter

The implementing part of the fault confinement mechanism of the CAN protocol. In case of an error during reception, this counter is incremented by 1 or by 8 depending on the error condition as defined by the CAN standard. After every successful reception the counter is decremented by 1 or reset to 120 if its value was higher than 128. When the counter value exceeds 127, the CAN controller enters the error passive state.

Bits 23:16 **TEC[7:0]**: Least significant byte of the 9-bit transmit error counter

The implementing part of the fault confinement mechanism of the CAN protocol.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **LEC[2:0]**: Last error code

This field is set by hardware and holds a code which indicates the error condition of the last error detected on the CAN bus. If a message has been transferred (reception or transmission) without error, this field is cleared to '0'.

The LEC[2:0] bits can be set to value 0b111 by software. They are updated by hardware to indicate the current communication status.

000: No Error

001: Stuff Error

010: Form Error

011: Acknowledgment Error

100: Bit recessive Error

101: Bit dominant Error

110: CRC Error

111: Set by software

Bit 3 Reserved, must be kept at reset value.

Bit 2 **BOFF**: Bus-off flag

This bit is set by hardware when it enters the bus-off state. The bus-off state is entered on TEC overflow, greater than 255, refer to [Section 32.7.6](#).

Bit 1 **EPVF**: Error passive flag

This bit is set by hardware when the Error Passive limit has been reached (Receive Error Counter or Transmit Error Counter > 127).

Bit 0 **EWGF**: Error warning flag

This bit is set by hardware when the warning limit has been reached (Receive Error Counter or Transmit Error Counter ≥ 96).

**CAN bit timing register (CAN\_BTR)**

Address offset: 0x1C

Reset value: 0x0123 0000

This register can only be accessed by the software when the CAN hardware is in initialization mode.

Bit 31 **SILM**: Silent mode (debug)

0: Normal operation  
1: Silent Mode

Bit 30 **LBKM**: Loop back mode (debug)

0: Loop Back Mode disabled  
1: Loop Back Mode enabled

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **SJW[1:0]**: Resynchronization jump width

These bits define the maximum number of time quanta the CAN hardware is allowed to lengthen or shorten a bit to perform the resynchronization.

$$t_{RJW} = t_q \times (SJW[1:0] + 1)$$

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **TS2[2:0]**: Time segment 2

These bits define the number of time quanta in Time Segment 2.

$$t_{BS2} = t_q \times (TS2[2:0] + 1)$$

Bits 19:16 **TS1[3:0]**: Time segment 1

These bits define the number of time quanta in Time Segment 1

$$t_{BS1} = t_q \times (TS1[3:0] + 1)$$

For more information on bit timing refer to [Section 32.7.7](#).

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **BRP[9:0]**: Baud rate prescaler

These bits define the length of a time quanta.

$$t_q = (BRP[9:0] + 1) \times t_{PCLK}$$

### 32.9.3 CAN mailbox registers

This chapter describes the registers of the transmit and receive mailboxes. Refer to [Section 32.7.5: Message storage](#) for detailed register mapping.

Transmit and receive mailboxes have the same registers except:

- The FMI field in the CAN\_RDTxR register.
- A receive mailbox is always write protected.
- A transmit mailbox is write-enabled only while empty, corresponding TME bit in the CAN\_TSR register set.

There are three TX Mailboxes and two RX Mailboxes, as shown in [Figure 349](#). Each RX Mailbox allows access to a 3-level depth FIFO, the access being offered only to the oldest received message in the FIFO. Each mailbox consist of four registers.

**Figure 349. RX and TX mailboxes**

**CAN TX mailbox identifier register (CAN\_TlRxR) (x=0..2)**

Address offsets: 0x180, 0x190, 0x1A0

Reset value: 0xFFFF XXXX (except bit 0, TXRQ = 0)

All TX registers are write protected when the mailbox is pending transmission (TMEx reset).

This register also implements the TX request control (bit 0) - reset value 0.

|                        |    |    |    |    |    |    |    |    |    |    |             |    |     |     |      |
|------------------------|----|----|----|----|----|----|----|----|----|----|-------------|----|-----|-----|------|
| 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20          | 19 | 18  | 17  | 16   |
| STID[10:0]/EXID[28:18] |    |    |    |    |    |    |    |    |    |    | EXID[17:13] |    |     |     |      |
| rw                     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw  | rw  | rw   |
| 15                     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4           | 3  | 2   | 1   | 0    |
| EXID[12:0]             |    |    |    |    |    |    |    |    |    |    |             |    | IDE | RTR | TXRQ |
| rw                     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw          | rw | rw  | rw  | rw   |

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bits 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.

Bit 2 **IDE**: Identifier extension

This bit defines the identifier type of message in the mailbox.

0: Standard identifier.

1: Extended identifier.

Bit 1 **RTR**: Remote transmission request

0: Data frame

1: Remote frame

Bit 0 **TXRQ**: Transmit mailbox request

Set by software to request the transmission for the corresponding mailbox.

Cleared by hardware when the mailbox becomes empty.

### CAN mailbox data length control and time stamp register (CAN\_TDTxR) (x=0..2)

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x184, 0x194, 0x1A4

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |     |          |    |    |    |          |    |    |
|------------|----|----|----|----|----|----|----|-----|----------|----|----|----|----------|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22       | 21 | 20 | 19 | 18       | 17 | 16 |
| TIME[15:0] |    |    |    |    |    |    |    |     |          |    |    |    |          |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw  | rw       | rw | rw | rw | rw       | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7   | 6        | 5  | 4  | 3  | 2        | 1  | 0  |
| Reserved   |    |    |    |    |    |    |    | TGT | Reserved |    |    |    | DLC[3:0] |    |    |
|            |    |    |    |    |    |    |    | rw  |          |    |    |    | rw       | rw | rw |

Bits 31:16 **TIME[15:0]**: Message time stamp

This field contains the 16-bit timer value captured at the SOF transmission.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **TGT**: Transmit global time

This bit is active only when the hardware is in the Time Trigger Communication mode, TTCM bit of the CAN\_MCR register is set.

0: Time stamp TIME[15:0] is not sent.

1: Time stamp TIME[15:0] value is sent in the last two data bytes of the 8-byte message:

TIME[7:0] in data byte 7 and TIME[15:8] in data byte 6, replacing the data written in CAN\_TDHxR[31:16] register (DATA6[7:0] and DATA7[7:0]). DLC must be programmed as 8 in order these two bytes to be sent over the CAN bus.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **DLC[3:0]**: Data length code

This field defines the number of data bytes a data frame contains or a remote frame request.

A message can contain from 0 to 8 data bytes, depending on the value in the DLC field.

**CAN mailbox data low register (CAN\_TDLxR) (x=0..2)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x188, 0x198, 0x1A8

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA3[7:0] |    |    |    |    |    |    |    | DATA2[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA1[7:0] |    |    |    |    |    |    |    | DATA0[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **DATA3[7:0]**: Data byte 3

Data byte 3 of the message.

Bits 23:16 **DATA2[7:0]**: Data byte 2

Data byte 2 of the message.

Bits 15:8 **DATA1[7:0]**: Data byte 1

Data byte 1 of the message.

Bits 7:0 **DATA0[7:0]**: Data byte 0

Data byte 0 of the message.

A message can contain from 0 to 8 data bytes and starts with byte 0.

**CAN mailbox data high register (CAN\_TDHxR) (x=0..2)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x18C, 0x19C, 0x1AC

Reset value: 0xFFFF XXXX

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA7[7:0] |    |    |    |    |    |    |    | DATA6[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA5[7:0] |    |    |    |    |    |    |    | DATA4[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw         | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **DATA7[7:0]**: Data byte 7

Data byte 7 of the message.

*Note: If TGT of this message and TTCM are active, DATA7 and DATA6 are replaced by the TIME stamp value.*

Bits 23:16 **DATA6[7:0]**: Data byte 6

Data byte 6 of the message.

Bits 15:8 **DATA5[7:0]**: Data byte 5

Data byte 5 of the message.

Bits 7:0 **DATA4[7:0]**: Data byte 4

Data byte 4 of the message.

**CAN receive FIFO mailbox identifier register (CAN\_RlRxR) (x=0..1)**

Address offsets: 0x1B0, 0x1C0

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|                        |    |    |    |    |    |    |    |    |    |    |             |    |     |     |      |
|------------------------|----|----|----|----|----|----|----|----|----|----|-------------|----|-----|-----|------|
| 31                     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20          | 19 | 18  | 17  | 16   |
| STID[10:0]/EXID[28:18] |    |    |    |    |    |    |    |    |    |    | EXID[17:13] |    |     |     |      |
| r                      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r           | r  | r   | r   | r    |
| 15                     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4           | 3  | 2   | 1   | 0    |

| r                      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r           | r  | r   | r   |      |

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bits 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.

Bit 2 **IDE**: Identifier extension

This bit defines the identifier type of message in the mailbox.

0: Standard identifier.

1: Extended identifier.

Bit 1 **RTR**: Remote transmission request

0: Data frame

1: Remote frame

Bit 0 Reserved, must be kept at reset value.

### CAN receive FIFO mailbox data length control and time stamp register (CAN\_RDTxR) (x=0..1)

Address offsets: 0x1B4, 0x1C4

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |          |    |    |    |          |    |    |    |
|------------|----|----|----|----|----|----|----|----------|----|----|----|----------|----|----|----|

Bits 31:16 **TIME[15:0]**: Message time stamp

This field contains the 16-bit timer value captured at the SOF detection.

Bits 15:8 **FMI[7:0]**: Filter match index

This register contains the index of the filter the message stored in the mailbox passed through. For more details on identifier filtering refer to [Section 32.7.4](#)

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **DLC[3:0]**: Data length code

This field defines the number of data bytes a data frame contains (0 to 8). It is 0 in the case of a remote frame request.

**CAN receive FIFO mailbox data low register (CAN\_RDLxR) (x=0..1)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x1B8, 0x1C8

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Bits 31:24 **DATA3[7:0]**: Data Byte 3

Data byte 3 of the message.

Bits 23:16 **DATA2[7:0]**: Data Byte 2

Data byte 2 of the message.

Bits 15:8 **DATA1[7:0]**: Data Byte 1

Data byte 1 of the message.

Bits 7:0 **DATA0[7:0]**: Data Byte 0

Data byte 0 of the message.

A message can contain from 0 to 8 data bytes and starts with byte 0.

**CAN receive FIFO mailbox data high register (CAN\_RDHxR) (x=0..1)**

Address offsets: 0x1BC, 0x1CC

Reset value: 0xFFFF XXXX

All RX registers are write protected.

|            |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

Bits 31:24 **DATA7[7:0]**: Data Byte 7

Data byte 3 of the message.

Bits 23:16 **DATA6[7:0]**: Data Byte 6

Data byte 2 of the message.

Bits 15:8 **DATA5[7:0]**: Data Byte 5

Data byte 1 of the message.

Bits 7:0 **DATA4[7:0]**: Data Byte 4

Data byte 0 of the message.

### 32.9.4 CAN filter registers

#### CAN filter master register (CAN\_FMR)

Address offset: 0x200

Reset value: 0x2A1C 0E01

All bits of this register are set and cleared by software.

|          |    |             |    |    |    |    |    |          |    |    |    |    |    |       |    |
|----------|----|-------------|----|----|----|----|----|----------|----|----|----|----|----|-------|----|
| 31       | 30 | 29          | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17    | 16 |
| Reserved |    |             |    |    |    |    |    |          |    |    |    |    |    |       |    |
| 15       | 14 | 13          | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1     | 0  |
| Reserved |    | CAN2SB[5:0] |    |    |    |    |    | Reserved |    |    |    |    |    | FINIT |    |
|          |    | rw          | rw | rw | rw | rw | rw |          |    |    |    |    |    | rw    |    |

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **CAN2SB[5:0]**: CAN2 start bank

These bits are set and cleared by software. They define the start bank for the CAN2 interface (Slave) in the range 0 to 27.

*Note: When CAN2SB[5:0] = 28d, all the filters to CAN1 can be used.*

*When CAN2SB[5:0] is set to 0, no filters are assigned to CAN1.*

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **FINIT**: Filter init mode

Initialization mode for filter banks

0: Active filters mode.

1: Initialization mode for the filters.

**CAN filter mode register (CAN\_FM1R)**

Address offset: 0x204

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|          |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|----------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31       | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |

|          |       |       |       | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    |
| 15       | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| FBM15    | FBM14 | FBM13 | FBM12 | FBM11 | FBM10 | FBM9  | FBM8  | FBM7  | FBM6  | FBM5  | FBM4  | FBM3  | FBM2  | FBM1  | FBM0  |
| rw       | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    | rw    |

Note: Refer to [Figure 342](#).

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FBMx**: Filter mode

Mode of the registers of Filter x.

0: Two 32-bit registers of filter bank x are in Identifier Mask mode.

1: Two 32-bit registers of filter bank x are in Identifier List mode.

**CAN filter scale register (CAN\_FS1R)**

Address offset: 0x20C

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|          |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FSCx**: Filter scale configuration

These bits define the scale configuration of Filters 13-0.

0: Dual 16-bit scale configuration

1: Single 32-bit scale configuration

Note: Refer to [Figure 342](#).

**CAN filter FIFO assignment register (CAN\_FFA1R)**

Address offset: 0x214

Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN\_FMR register.

|          |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FFAx**: Filter FIFO assignment for filter x

The message passing through this filter is stored in the specified FIFO.

0: Filter assigned to FIFO 0

1: Filter assigned to FIFO 1

**CAN filter activation register (CAN\_FA1R)**

Address offset: 0x21C

Reset value: 0x0000 0000

|          |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|----------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 31       | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:0 **FACTx**: Filter active

The software sets this bit to activate Filter x. To modify the Filter x registers (CAN\_FxR[0:7]), the FACTx bit must be cleared or the FINIT bit of the CAN\_FMR register must be set.

0: Filter x is not active

1: Filter x is active

**Filter bank i register x (CAN\_FiRx) (i=0..27, x=1, 2)**

Address offsets: 0x240..0x31C

Reset value: 0xFFFF FFFF

There are 28 filter banks, i=0 .. 27. Each filter bank i is composed of two 32-bit registers, CAN\_FiR[2:1].

This register can only be modified when the FACTx bit of the CAN\_FAxR register is cleared or when the FINIT bit of the CAN\_FMR register is set.

|      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

In all configurations:

Bits 31:0 **FB[31:0]**: Filter bits

**Identifier**

Each bit of the register specifies the level of the corresponding bit of the expected identifier.

0: Dominant bit is expected

1: Recessive bit is expected

**Mask**

Each bit of the register specifies whether the bit of the associated identifier register must match with the corresponding bit of the expected identifier or not.

0: Don't care, the bit is not used for the comparison

1: Must match, the bit of the incoming identifier must have the same level as specified in the corresponding identifier register of the filter.

**Note:** *Depending on the scale and mode configuration of the filter the function of each register can differ. For the filter mapping, functions description and mask registers association, refer to [Section 32.7.4](#).*

A Mask/Identifier register in **mask mode** has the same bit mapping as in **identifier list mode**.

*For the register mapping/addresses of the filter banks refer to [Table 185](#).*

### 32.9.5 bxCAN register map

Refer to [Section 2.3: Memory map](#) for the register boundary addresses. The registers from offset 0x200 to 31C are present only in CAN1.

**Table 185. bxCAN register map and reset values**

| Offset      | Register    | 31                     | 30   | 29       | 28 | 27 | 26        | 25       | 24    | 23         | 22       | 21 | 20 | 19         | 18       | 17    | 16    | 15         | 14       | 13       | 12   | 11 | 10    | 9     | 8        | 7          | 6     | 5        | 4        | 3        | 2     | 1         | 0      |       |        |       |

## **33 Ethernet (ETH): media access control (MAC) with DMA controller**

This section applies only to STM32F42xx/F43xx and STM32F407x/F417x devices.

### **33.1 Ethernet introduction**

Portions Copyright (c) 2004, 2005 Synopsys, Inc. All rights reserved. Used with permission.

The Ethernet peripheral enables the STM32F4xx to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2002 standard.

The Ethernet provides a configurable, flexible peripheral to meet the needs of various applications and customers. It supports two industry standard interfaces to the external physical layer (PHY): the default media independent interface (MII) defined in the IEEE 802.3 specifications and the reduced media independent interface (RMII). It can be used in number of applications such as switches, network interface cards, etc.

The Ethernet is compliant with the following standards:

- IEEE 802.3-2002 for Ethernet MAC
- IEEE 1588-2008 standard for precision networked clock synchronization
- AMBA 2.0 for AHB Master/Slave ports
- RMII specification from RMII consortium

### **33.2 Ethernet main features**

The Ethernet (ETH) peripheral includes the following features, listed by category:

### 33.2.1 MAC core features

- Supports 10/100 Mbit/s data transfer rates with external PHY interfaces
- IEEE 802.3-compliant MII interface to communicate with an external Fast Ethernet PHY
- Supports both full-duplex and half-duplex operations
  - Supports CSMA/CD Protocol for half-duplex operation
  - Supports IEEE 802.3x flow control for full-duplex operation
  - Optional forwarding of received pause control frames to the user application in full-duplex operation
  - Back-pressure support for half-duplex operation
  - Automatic transmission of zero-quanta pause frame on deassertion of flow control input in full-duplex operation
- Preamble and start-of-frame data (SFD) insertion in Transmit, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Options for automatic pad/CRC stripping on receive frames
- Programmable frame length to support Standard frames with sizes up to 16 KB
- Programmable interframe gap (40-96 bit times in steps of 8)
- Supports a variety of flexible address filtering modes:
  - Up to four 48-bit perfect (DA) address filters with masks for each byte
  - Up to three 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter (optional) for multicast and unicast (DA) addresses
  - Option to pass all multicast addressed frames
  - Promiscuous mode support to pass all frames without any filtering for network monitoring
  - Passes all incoming packets (as per filter) with a status report
- Separate 32-bit status returned for transmission and reception packets
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Separate transmission, reception, and control interfaces to the Application
- Supports mandatory network statistics with RMON/MIB counters (RFC2819/RFC2665)
- MDIO interface for PHY device configuration and management
- Detection of LAN wake-up frames and AMD Magic Packet™ frames
- Receive feature for checksum off-load for received IPv4 and TCP packets encapsulated by the Ethernet frame
- Enhanced receive feature for checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagrams
- Support Ethernet frame time stamping as described in IEEE 1588-2008. Sixty-four-bit time stamps are given in each frame's transmit or receive status
- Two sets of FIFOs: a 2-KB Transmit FIFO with programmable threshold capability, and a 2-KB Receive FIFO with a configurable threshold (default of 64 bytes)
- Receive Status vectors inserted into the Receive FIFO after the EOF transfer enables multiple-frame storage in the Receive FIFO without requiring another FIFO to store those frames' Receive Status
- Option to filter all error frames on reception and not forward them to the application in

#### Store-and-Forward mode

- Option to forward under-sized good frames
- Supports statistics by generating pulses for frames dropped or corrupted (due to overflow) in the Receive FIFO
- Supports Store and Forward mechanism for transmission to the MAC core
- Automatic generation of PAUSE frame control or back pressure signal to the MAC core based on Receive FIFO-fill (threshold configurable) level
- Handles automatic retransmission of Collision frames for transmission
- Discards frames on late collision, excessive collisions, excessive deferral and underrun conditions
- Software control to flush Tx FIFO
- Calculates and inserts IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode
- Supports internal loopback on the MII for debugging

### 33.2.2 DMA features

- Supports all AHB burst types in the AHB Slave Interface
- Software can select the type of AHB burst (fixed or indefinite burst) in the AHB Master interface.
- Option to select address-aligned bursts from AHB master port
- Optimization for packet-oriented DMA transfers with frame delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptor architecture, allowing large blocks of data transfer with minimum CPU intervention;
- each descriptor can transfer up to 8 KB of data
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst size for Transmit and Receive DMA Engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-frame Transmit/Receive complete interrupt control
- Round-robin or fixed-priority arbitration between Receive and Transmit engines
- Start/Stop modes
- Current Tx/Rx buffer pointer as status registers
- Current Tx/Rx descriptor pointer as status registers

### 33.2.3 PTP features

- Received and transmitted frames time stamping
- Coarse and fine correction methods
- Trigger interrupt when system time becomes greater than target time
- Pulse per second output (product alternate function output)

### 33.3 Ethernet pins

[Table 186](#) shows the MAC signals and the corresponding MII/RMII signal mapping. All MAC signals are mapped onto AF11, some signals are mapped onto different I/O pins, and should be configured in Alternate function mode (for more details, refer to [Section 8.3.2: I/O pin multiplexer and mapping](#)).

**Table 186. Alternate function mapping**

| Port     | AF11                              |
|----------|-----------------------------------|
|          | ETH                               |
| PA0-WKUP | ETH_MII_CRS                       |
| PA1      | ETH_MII_RX_CLK / ETH_RMII_REF_CLK |
| PA2      | ETH_MDIO                          |
| PA3      | ETH_MII_COL                       |
| PA7      | ETH_MII_RX_DV / ETH_RMII_CRS_DV   |
| PB0      | ETH_MII_RXD2                      |
| PB1      | ETH_MII_RXD3                      |
| PB5      | ETH_PPS_OUT                       |
| PB8      | ETH_MII_TXD3                      |
| PB10     | ETH_MII_RX_ER                     |
| PB11     | ETH_MII_TX_EN / ETH_RMII_TX_EN    |
| PB12     | ETH_MII_TXD0 / ETH_RMII_TXD0      |
| PB13     | ETH_MII_TXD1 / ETH_RMII_TXD1      |
| PC1      | ETH_MDC                           |
| PC2      | ETH_MII_TXD2                      |
| PC3      | ETH_MII_TX_CLK                    |
| PC4      | ETH_MII_RXD0 / ETH_RMII_RXD0      |
| PC5      | ETH_MII_RXD1 / ETH_RMII_RXD1      |
| PE2      | ETH_MII_TXD3                      |
| PG8      | ETH_PPS_OUT                       |
| PG11     | ETH_MII_TX_EN / ETH_RMII_TX_EN    |
| PG13     | ETH_MII_TXD0 / ETH_RMII_TXD0      |
| PG14     | ETH_MII_TXD1 / ETH_RMII_TXD1      |
| PH2      | ETH_MII_CRS                       |
| PH3      | ETH_MII_COL                       |
| PH6      | ETH_MII_RXD2                      |
| PH7      | ETH_MII_RXD3                      |
| PI10     | ETH_MII_RX_ER                     |

### 33.4 Ethernet functional description: SMI, MII and RMII

The Ethernet peripheral consists of a MAC 802.3 (media access control) with a dedicated DMA controller. It supports both default media-independent interface (MII) and reduced media-independent interface (RMII) through one selection bit (refer to SYSCFG\_PMC register).

The DMA controller interfaces with the Core and memories through the AHB Master and Slave interfaces. The AHB Master Interface controls data transfers while the AHB Slave interface accesses Control and Status registers (CSR) space.

The Transmit FIFO (Tx FIFO) buffers data read from system memory by the DMA before transmission by the MAC Core. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they are transferred to system memory by the DMA.

The Ethernet peripheral also includes an SMI to communicate with external PHY. A set of configuration registers permit the user to select the desired mode and features for the MAC and the DMA controller.

**Note:** The AHB clock frequency must be at least 25 MHz when the Ethernet is used.

**Figure 350. ETH block diagram**

1. For AHB connections refer to [Figure 1: System architecture for STM32F405xx/07xx and STM32F415xx/17xx devices](#) and [Figure 2: System architecture for STM32F42xxx and STM32F43xxx devices](#).

#### 33.4.1 Station management interface: SMI

The station management interface (SMI) allows the application to access any PHY registers through a 2-wire clock and data lines. The interface supports accessing up to 32 PHYs.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time.

Both the MDC clock line and the MDIO data line are implemented as alternate function I/O in the microcontroller:

- MDC: a periodic clock that provides the timing reference for the data transfer at the maximum frequency of 2.5 MHz. The minimum high and low times for MDC must be

160 ns each, and the minimum period for MDC must be 400 ns. In idle state the SMI management interface drives the MDC clock signal low.

- MDIO: data input/output bitstream to transfer status information to/from the PHY device synchronously with the MDC clock signal

Figure 351. SMI interface signals

### SMI frame format

The frame structure related to a read or write operation is shown in [Table 187](#), the order of bit transmission must be from left to right.

Table 187. Management frame format

|       | Management frame fields |       |           |       |       |    |                 |      |
|-------|-------------------------|-------|-----------|-------|-------|----|-----------------|------|
|       | Preamble (32 bits)      | Start | Operation | PADDR | RADDR | TA | Data (16 bits)  | Idle |
| Read  | 1... 1                  | 01    | 10        | ppppp | rrrrr | Z0 | ddddddddddddddd | Z    |
| Write | 1... 1                  | 01    | 01        | ppppp | rrrrr | 10 | ddddddddddddddd | Z    |

The management frame consists of eight fields:

- **Preamble:** each transaction (read or write) can be initiated with the preamble field that corresponds to 32 contiguous logic one bits on the MDIO line with 32 corresponding cycles on MDC. This field is used to establish synchronization with the PHY device.
- **Start:** the start of frame is defined by a <01> pattern to verify transitions on the line from the default logic one state to zero and back to one.
- **Operation:** defines the type of transaction (read or write) in progress.
- **PADDR:** the PHY address is 5 bits, allowing 32 unique PHY addresses. The MSB bit of the address is the first transmitted and received.
- **RADDR:** the register address is 5 bits, allowing 32 individual registers to be addressed within the selected PHY device. The MSB bit of the address is the first transmitted and received.
- **TA:** the turn-around field defines a 2-bit pattern between the RADDR and DATA fields to avoid contention during a read transaction. For a read transaction the MAC controller drives high-impedance on the MDIO line for the 2 bits of TA. The PHY device must drive a high-impedance state on the first bit of TA, a zero bit on the second one.

For a write transaction, the MAC controller drives a <10> pattern during the TA field. The PHY device must drive a high-impedance state for the 2 bits of TA.

- **Data:** the data field is 16-bit. The first bit transmitted and received must be bit 15 of the ETH\_MIID register.
- **Idle:** the MDIO line is driven in high-impedance state. All three-state drivers must be disabled and the PHY's pull-up resistor keeps the line at logic one.

### SMI write operation

When the application sets the MII Write and Busy bits (in *Ethernet MAC MII address register (ETH\_MACMIAR)*), the SMI initiates a write operation into the PHY registers by transferring the PHY address, the register address in PHY, and the write data (in *Ethernet MAC MII data register (ETH\_MACMIIDR)*). The application should not change the MII Address register contents or the MII Data register while the transaction is ongoing. Write operations to the MII Address register or the MII Data register during this period are ignored (the Busy bit is high), and the transaction is completed without any error. After the Write operation has completed, the SMI indicates this by resetting the Busy bit.

Figure 352 shows the frame format for the write operation.

**Figure 352. MDIO timing and frame structure - Write cycle**

ai15626

### SMI read operation

When the user sets the MII Busy bit in the Ethernet MAC MII address register (ETH\_MACMIAR) with the MII Write bit at 0, the SMI initiates a read operation in the PHY registers by transferring the PHY address and the register address in PHY. The application should not change the MII Address register contents or the MII Data register while the transaction is ongoing. Write operations to the MII Address register or MII Data register during this period are ignored (the Busy bit is high) and the transaction is completed without any error. After the read operation has completed, the SMI resets the Busy bit and then updates the MII Data register with the data read from the PHY.

Figure 353 shows the frame format for the read operation.

Figure 353. MDIO timing and frame structure - Read cycle

### SMI clock selection

The MAC initiates the Management Write/Read operation. The SMI clock is a divided clock whose source is the application clock (AHB clock). The divide factor depends on the clock range setting in the MII Address register.

Table 188 shows how to set the clock ranges.

Table 188. Clock range

| Selection     | HCLK clock  | MDC clock       |
|---------------|-------------|-----------------|
| 000           | 60-100 MHz  | AHB clock / 42  |
| 001           | 100-150 MHz | AHB clock / 62  |
| 010           | 20-35 MHz   | AHB clock / 16  |
| 011           | 35-60 MHz   | AHB clock / 26  |
| 100           | 150-180 MHz | AHB clock / 102 |
| 101, 110, 111 | Reserved    | -               |

### 33.4.2 Media-independent interface: MII

The media-independent interface (MII) defines the interconnection between the MAC sublayer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

Figure 354. Media independent interface signals

- **MII\_TX\_CLK**: continuous clock that provides the timing reference for the TX data transfer. The nominal frequency is: 2.5 MHz at 10 Mbit/s speed; 25 MHz at 100 Mbit/s speed.
- **MII\_RX\_CLK**: continuous clock that provides the timing reference for the RX data transfer. The nominal frequency is: 2.5 MHz at 10 Mbit/s speed; 25 MHz at 100 Mbit/s speed.
- **MII\_TX\_EN**: transmission enable indicates that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (**MII\_TX\_CLK**) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- **MII\_TXD[3:0]**: transmit data is a bundle of 4 data signals driven synchronously by the MAC sublayer and qualified (valid data) on the assertion of the **MII\_TX\_EN** signal. **MII\_TXD[0]** is the least significant bit, **MII\_TXD[3]** is the most significant bit. While **MII\_TX\_EN** is deasserted the transmit data must have no effect upon the PHY.
- **MII\_CRS**: carrier sense is asserted by the PHY when either the transmit or receive medium is non idle. It shall be deasserted by the PHY when both the transmit and receive media are idle. The PHY must ensure that the **MII\_CS** signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the TX and RX clocks. In full duplex mode the state of this signal is don't care for the MAC sublayer.
- **MII\_COL**: collision detection must be asserted by the PHY upon detection of a collision on the medium and must remain asserted while the collision condition persists. This signal is not required to transition synchronously with respect to the TX and RX clocks. In full duplex mode the state of this signal is don't care for the MAC sublayer.
- **MII\_RXD[3:0]**: reception data is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the **MII\_RX\_DV** signal. **MII\_RXD[0]** is the least significant bit, **MII\_RXD[3]** is the most significant bit. While **MII\_RX\_EN** is deasserted and **MII\_RX\_ER** is asserted, a specific **MII\_RXD[3:0]** value is used to transfer specific information from the PHY (see [Table 190](#)).
- **MII\_RX\_DV**: receive data valid indicates that the PHY is presenting recovered and decoded nibbles on the MII for reception. It must be asserted synchronously (**MII\_RX\_CLK**) with the first recovered nibble of the frame and must remain asserted through the final recovered nibble. It must be deasserted prior to the first clock cycle that follows the final nibble. In order to receive the frame correctly, the **MII\_RX\_DV** signal must encompass the frame, starting no later than the SFD field.
- **MII\_RX\_ER**: receive error must be asserted for one or more clock periods (**MII\_RX\_CLK**) to indicate to the MAC sublayer that an error was detected somewhere in the frame. This error condition must be qualified by **MII\_RX\_DV** assertion as described in [Table 190](#).

**Table 189. TX interface signal encoding**

| <b>MII_TX_EN</b> | <b>MII_TXD[3:0]</b> | <b>Description</b>       |
|------------------|---------------------|--------------------------|
| 0                | 0000 through 1111   | Normal inter-frame       |
| 1                | 0000 through 1111   | Normal data transmission |

Table 190. RX interface signal encoding

| MII_RX_DV | MII_RX_ERR | MII_RXD[3:0]      | Description                |
|-----------|------------|-------------------|----------------------------|
| 0         | 0          | 0000 through 1111 | Normal inter-frame         |
| 0         | 1          | 0000              | Normal inter-frame         |
| 0         | 1          | 0001 through 1101 | Reserved                   |
| 0         | 1          | 1110              | False carrier indication   |
| 0         | 1          | 1111              | Reserved                   |
| 1         | 0          | 0000 through 1111 | Normal data reception      |
| 1         | 1          | 0000 through 1111 | Data reception with errors |

### MII clock sources

To generate both TX\_CLK and RX\_CLK clock signals, the external PHY must be clocked with an external 25 MHz as shown in [Figure 355](#). Instead of using an external 25 MHz quartz to provide this clock, the STM32F4xxmicrocontroller can output this signal on its MCO pin. In this case, the PLL multiplier has to be configured so as to get the desired frequency on the MCO pin, from the 25 MHz external quartz.

Figure 355. MII clock sources

### 33.4.3 Reduced media-independent interface: RMII

The reduced media-independent interface (RMII) specification reduces the pin count between the microcontroller Ethernet peripheral and the external Ethernet in 10/100 Mbit/s. According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. The RMII specification is dedicated to reduce the pin count to 7 pins (a 62.5% decrease in pin count).

The RMII is instantiated between the MAC and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:

- It supports 10-Mbit/s and 100-Mbit/s operating rates
- The clock reference must be doubled to 50 MHz
- The same clock reference must be sourced externally to both MAC and external Ethernet PHY
- It provides independent 2-bit wide (dibit) transmit and receive data paths

**Figure 356. Reduced media-independent interface signals**

#### RMII clock sources

Either clock the PHY from an external 50 MHz clock or use a PHY with an embedded PLL to generate the 50 MHz frequency.

**Figure 357. RMII clock sources**

### 33.4.4 MII/RMII selection

The mode, MII or RMII, is selected using the configuration bit 23, MII\_RMII\_SEL, in the SYSCFG\_PMC register. The application has to set the MII/RMII mode while the Ethernet controller is under reset or before enabling the clocks.

### MII/RMII internal clock scheme

The clock scheme required to support both the MII and RMII, as well as 10 and 100 Mbit/s operations is described in [Figure 358](#).

**Figure 358. Clock scheme**

1. The MII/RMII selection is controlled through bit 23, MII\_RMII\_SEL, in the SYSCFG\_PMC register.

To save a pin, the two input clock signals, RMII\_REF\_CLK and MII\_RX\_CLK, are multiplexed on the same GPIO pin.

## 33.5 Ethernet functional description: MAC 802.3

The IEEE 802.3 International Standard for local area networks (LANs) employs the CSMA/CD (carrier sense multiple access with collision detection) as the access method.

The Ethernet peripheral consists of a MAC 802.3 (media access control) controller with media independent interface (MII) and a dedicated DMA controller.

The MAC block implements the LAN CSMA/CD sublayer for the following families of systems: 10 Mbit/s and 100 Mbit/s of data rates for baseband and broadband systems. Half- and full-duplex operation modes are supported. The collision detection access method is applied only to the half-duplex operation mode. The MAC control frame sublayer is supported.

The MAC sublayer performs the following functions associated with a data link control procedure:

- Data encapsulation (transmit and receive)
  - Framing (frame boundary delimitation, frame synchronization)
  - Addressing (handling of source and destination addresses)
  - Error detection
- Media access management
  - Medium allocation (collision avoidance)
  - Contention resolution (collision handling)

Basically there are two operating modes of the MAC sublayer:

- Half-duplex mode: the stations contend for the use of the physical medium, using the CSMA/CD algorithms.
- Full duplex mode: simultaneous transmission and reception without contention resolution (CSMA/CD algorithm are unnecessary) when all the following conditions are met:
  - physical medium capability to support simultaneous transmission and reception
  - exactly 2 stations connected to the LAN
  - both stations configured for full-duplex operation

### 33.5.1 MAC 802.3 frame format

The MAC block implements the MAC sublayer and the optional MAC control sublayer (10/100 Mbit/s) as specified by the IEEE 802.3-2002 standard.

Two frame formats are specified for data communication systems using the CSMA/CD MAC:

- Basic MAC frame format
- Tagged MAC frame format (extension of the basic MAC frame format)

[Figure 360](#) and [Figure 361](#) describe the frame structure (untagged and tagged) that includes the following fields:

- Preamble: 7-byte field used for synchronization purposes (PLS circuitry)  
Hexadecimal value: 55-55-55-55-55-55-55  
Bit pattern: 01010101 01010101 01010101 01010101 01010101 01010101 01010101  
(right-to-left bit transmission)
- Start frame delimiter (SFD): 1-byte field used to indicate the start of a frame.  
Hexadecimal value: D5  
Bit pattern: 11010101 (right-to-left bit transmission)
- Destination and Source Address fields: 6-byte fields to indicate the destination and source station addresses as follows (see [Figure 359](#)):
  - Each address is 48 bits in length
  - The first LSB bit (I/G) in the destination address field is used to indicate an individual (I/G = 0) or a group address (I/G = 1). A group address could identify none, one or more, or all the stations connected to the LAN. In the source address the first bit is reserved and reset to 0.
  - The second bit (U/L) distinguishes between locally (U/L = 1) or globally (U/L = 0) administered addresses. For broadcast addresses this bit is also 1.
  - Each byte of each address field must be transmitted least significant bit first.

The address designation is based on the following types:

- Individual address: this is the physical address associated with a particular station on the network.
- Group address. A multideestination address associated with one or more stations on a given network. There are two kinds of multicast address:
  - Multicast-group address: an address associated with a group of logically related stations.
  - Broadcast address: a distinguished, predefined multicast address (all 1's in the destination address field) that always denotes all the stations on a given LAN.

Figure 359. Address field format

- QTag Prefix: 4-byte field inserted between the Source address field and the MAC Client Length/Type field. This field is an extension of the basic frame (untagged) to obtain the tagged MAC frame. The untagged MAC frames do not include this field. The extensions for tagging are as follows:
  - 2-byte constant Length/Type field value consistent with the Type interpretation (greater than 0x0600) equal to the value of the 802.1Q Tag Protocol Type (0x8100 hexadecimal). This constant field is used to distinguish tagged and untagged MAC frames.
  - 2-byte field containing the Tag control information field subdivided as follows: a 3-bit user priority, a canonical format indicator (CFI) bit and a 12-bit VLAN Identifier. The length of the tagged MAC frame is extended by 4 bytes by the QTag Prefix.
- MAC client length/type: 2-byte field with different meaning (mutually exclusive), depending on its value:
  - If the value is less than or equal to maxValidFrame (0d1500) then this field indicates the number of MAC client data bytes contained in the subsequent data field of the 802.3 frame (length interpretation).
  - If the value is greater than or equal to MinTypeValue (0d1536 decimal, 0x0600) then this field indicates the nature of the MAC client protocol (Type interpretation) related to the Ethernet frame.

Regardless of the interpretation of the length/type field, if the length of the data field is less than the minimum required for proper operation of the protocol, a PAD field is added after the data field but prior to the FCS (frame check sequence) field. The length/type field is transmitted and received with the higher-order byte first.

For length/type field values in the range between maxValidLength and minTypeValue (boundaries excluded), the behavior of the MAC sublayer is not specified: they may or may not be passed by the MAC sublayer.

- Data and PAD fields: n-byte data field. Full data transparency is provided, it means that any arbitrary sequence of byte values may appear in the data field. The size of the PAD, if any, is determined by the size of the data field. Max and min length of the data and PAD field are:
  - Maximum length = 1500 bytes
  - Minimum length for untagged MAC frames = 46 bytes
  - Minimum length for tagged MAC frames = 42 bytes

When the data field length is less than the minimum required, the PAD field is added to match the minimum length (42 bytes for tagged frames, 46 bytes for untagged frames).

- Frame check sequence: 4-byte field that contains the cyclic redundancy check (CRC) value. The CRC computation is based on the following fields: source address, destination address, QTag prefix, length/type, LLC data and PAD (that is, all fields except the preamble, SFD). The generating polynomial is the following:

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The CRC value of a frame is computed as follows:

- The first 2 bits of the frame are complemented
- The n-bits of the frame are the coefficients of a polynomial  $M(x)$  of degree  $(n - 1)$ . The first bit of the destination address corresponds to the  $x^{n-1}$  term and the last bit of the data field corresponds to the  $x^0$  term
- $M(x)$  is multiplied by  $x^{32}$  and divided by  $G(x)$ , producing a remainder  $R(x)$  of degree  $\leq 31$
- The coefficients of  $R(x)$  are considered as a 32-bit sequence
- The bit sequence is complemented and the result is the CRC
- The 32-bits of the CRC value are placed in the frame check sequence. The  $x^{32}$  term is the first transmitted, the  $x^0$  term is the last one

**Figure 360. MAC frame format**

### Figure 361. Tagged MAC frame format

Each byte of the MAC frame, except the FCS field, is transmitted low-order bit first.

An invalid MAC frame is defined by one of the following conditions:

- The frame length is inconsistent with the expected value as specified by the length/type field. If the length/type field contains a type value, then the frame length is assumed to be consistent with this field (no invalid frame)
- The frame length is not an integer number of bytes (extra bits)
- The CRC value computed on the incoming frame does not match the included FCS

### 33.5.2 MAC frame transmission

The DMA controls all transactions for the transmit path. Ethernet frames read from the system memory are pushed into the FIFO by the DMA. The frames are then popped out and transferred to the MAC core. When the end-of-frame is transferred, the status of the transmission is taken from the MAC core and transferred back to the DMA. The Transmit FIFO has a depth of 2 Kbyte. FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, using the AHB interface. The data from the AHB Master interface is pushed into the FIFO.

When the SOF is detected, the MAC accepts the data and begins transmitting to the MII. The time required to transmit the frame data to the MII after the application initiates transmission is variable, depending on delay factors like IFG delay, time to transmit preamble/SFD, and any back-off delays for Half-duplex mode. After the EOF is transferred to the MAC core, the core completes normal transmission and then gives the status of transmission back to the DMA. If a normal collision (in Half-duplex mode) occurs during transmission, the MAC core makes the transmit status valid, then accepts and drops all further data until the next SOF is received. The same frame should be retransmitted from SOF on observing a Retry request (in the Status) from the MAC. The MAC issues an underflow status if the data are not provided continuously during the transmission. During the normal transfer of a frame, if the MAC receives an SOF without getting an EOF for the previous frame, then the SOF is ignored and the new frame is considered as the continuation of the previous frame.

There are two modes of operation for popping data towards the MAC core:

- In Threshold mode, as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC core. The threshold level is configured using the TTC bits of ETH\_DMABMR.
- In Store-and-forward mode, only after a complete frame is stored in the FIFO, the frame is popped towards the MAC core. If the Tx FIFO size is smaller than the Ethernet frame to be transmitted, then the frame is popped towards the MAC core when the Tx FIFO becomes almost full.

The application can flush the Transmit FIFO of all contents by setting the FTF (ETH\_DMAOMR register [20]) bit. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer to the MAC core, then transfer is stopped as the FIFO is considered to be empty. Hence an underflow event occurs at the MAC transmitter and the corresponding Status word is forwarded to the DMA.

### Automatic CRC and pad generation

When the number of bytes received from the application falls below 60 (DA+SA+LT+Data), zeros are appended to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The MAC can be programmed not to append any padding. The cyclic redundancy check (CRC) for the frame check sequence (FCS) field is calculated and appended to the data being transmitted. When the MAC is programmed to not append the CRC value to the end of Ethernet frames, the computed CRC is not transmitted. An exception to this rule is that when the MAC is programmed to append pads for frames (DA+SA+LT+Data) less than 60 bytes, CRC is appended at the end of the padded frames.

The CRC generator calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

### Transmit protocol

The MAC controls the operation of Ethernet frame transmission. It performs the following functions to meet the IEEE 802.3/802.3z specifications. It:

- generates the preamble and SFD
- generates the jam pattern in Half-duplex mode
- controls the Jabber timeout
- controls the flow for Half-duplex mode (back pressure)
- generates the transmit frame status
- contains time stamp snapshot logic in accordance with IEEE 1588

When a new frame transmission is requested, the MAC sends out the preamble and SFD, followed by the data. The preamble is defined as 7 bytes of 0b10101010 pattern, and the SFD is defined as 1 byte of 0b10101011 pattern. The collision window is defined as 1 slot time (512 bit times for 10/100 Mbit/s Ethernet). The jam pattern generation is applicable only to Half-duplex mode, not to Full-duplex mode.

In MII mode, if a collision occurs at any time from the beginning of the frame to the end of the CRC field, the MAC sends a 32-bit jam pattern of 0x5555 5555 on the MII to inform all

other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the MAC completes the transmission of the preamble and SFD and then sends the jam pattern.

A jabber timer is maintained to cut off the transmission of Ethernet frames if more than 2048 (default) bytes have to be transferred. The MAC uses the deferral mechanism for flow control (back pressure) in Half-duplex mode. When the application requests to stop receiving frames, the MAC sends a JAM pattern of 32 bytes whenever it senses the reception of a frame, provided that transmit flow control is enabled. This results in a collision and the remote station backs off. The application requests flow control by setting the BPA bit (bit 0) in the ETH\_MACFCR register. If the application requests a frame to be transmitted, then it is scheduled and transmitted even when back pressure is activated. Note that if back pressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations abort their transmissions due to excessive collisions. If IEEE 1588 time stamping is enabled for the transmit frame, this block takes a snapshot of the system time when the SFD is put onto the transmit MII bus.

### Transmit scheduler

The MAC is responsible for scheduling the frame transmission on the MII. It maintains the interframe gap between two transmitted frames and follows the truncated binary exponential backoff algorithm for Half-duplex mode. The MAC enables transmission after satisfying the IFG and backoff delays. It maintains an idle period of the configured interframe gap (IFG bits in the ETH\_MACCCR register) between any two transmitted frames. If frames to be transmitted arrive sooner than the configured IFG time, the MII waits for the enable signal from the MAC before starting the transmission on it. The MAC starts its IFG counter as soon as the carrier signal of the MII goes inactive. At the end of the programmed IFG value, the MAC enables transmission in Full-duplex mode. In Half-duplex mode and when IFG is configured for 96 bit times, the MAC follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3 specification. The MAC resets its IFG counter if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the MAC continues the IFG count and enables the transmitter after the IFG interval. The MAC implements the truncated binary exponential backoff algorithm when it operates in Half-duplex mode.

### Transmit flow control

When the Transmit Flow Control Enable bit (TFE bit in ETH\_MACFCR) is set, the MAC generates Pause frames and transmits them as necessary, in Full-duplex mode. The Pause frame is appended with the calculated CRC, and is sent. Pause frame generation can be initiated in two ways.

A pause frame is sent either when the application sets the FCB bit in the ETH\_MACFCR register or when the receive FIFO is full (packet buffer).

- If the application has requested flow control by setting the FCB bit in ETH\_MACFCR, the MAC generates and transmits a single Pause frame. The value of the pause time in the generated frame contains the programmed pause time value in ETH\_MACFCR. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time value (PT in ETH\_MACFCR register) with the appropriate value.
- If the application has requested flow control when the receive FIFO is full, the MAC generates and transmits a Pause frame. The value of the pause time in the generated frame is the programmed pause time value in ETH\_MACFCR. If the receive FIFO

remains full at a configurable number of slot-times (PLT bits in ETH\_MACFCR) before this Pause time runs out, a second Pause frame is transmitted. The process is repeated as long as the receive FIFO remains full. If this condition is no more satisfied prior to the sampling time, the MAC transmits a Pause frame with zero pause time to indicate to the remote end that the receive buffer is ready to receive new data frames.

### Single-packet transmit operation

The general sequence of events for a transmit operation is as follows:

1. If the system has data to be transferred, the DMA controller fetches them from the memory through the AHB Master interface and starts forwarding them to the FIFO. It continues to receive the data until the end of frame is transferred.
2. When the threshold level is crossed or a full packet of data is received into the FIFO, the frame data are popped and driven to the MAC core. The DMA continues to transfer data from the FIFO until a complete packet has been transferred to the MAC. Upon completion of the frame, the DMA controller is notified by the status coming from the MAC.

### Transmit operation—Two packets in the buffer

1. Because the DMA must update the descriptor status before releasing it to the Host, there can be at the most two frames inside a transmit FIFO. The second frame is fetched by the DMA and put into the FIFO only if the OSF (operate on second frame) bit is set. If this bit is not set, the next frame is fetched from the memory only after the MAC has completely processed the frame and the DMA has released the descriptors.
2. If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. In the meantime, the second frame is received into the FIFO while the first frame is being transmitted. As soon as the first frame has been transferred and the status is received from the MAC, it is pushed to the DMA. If the DMA has already completed sending the second packet to the FIFO, the second transmission must wait for the status of the first packet before proceeding to the next frame.

### Retransmission during collision

While a frame is being transferred to the MAC, a collision event may occur on the MAC line interface in Half-duplex mode. The MAC would then indicate a retry attempt by giving the status even before the end of frame is received. Then the retransmission is enabled and the frame is popped out again from the FIFO. After more than 96 bytes have been popped towards the MAC core, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the MAC core indicates a late collision event.

### Transmit FIFO flush operation

The MAC provides a control to the software to flush the Transmit FIFO through the use of Bit 20 in the Operation mode register. The Flush operation is immediate and the Tx FIFO and the corresponding pointers are cleared to the initial state even if the Tx FIFO is in the middle of transferring a frame to the MAC Core. This results in an underflow event in the MAC transmitter, and the frame transmission is aborted. The status of such a frame is marked with both underflow and frame flush events (TDES0 bits 13 and 1). No data are coming to the FIFO from the application (DMA) during the Flush operation. Transfer transmit status words are transferred to the application for the number of frames that is flushed (including partial frames). Frames that are completely flushed have the Frame flush status bit (TDES0 13) set. The Flush operation is completed when the application (DMA) has accepted all of

the Status words for the frames that were flushed. The Transmit FIFO Flush control register bit is then cleared. At this point, new frames from the application (DMA) are accepted. All data presented for transmission after a Flush operation are discarded unless they start with an SOF marker.

### Transmit status word

At the end of the Ethernet frame transfer to the MAC core and after the core has completed the transmission of the frame, the transmit status is given to the application. The detailed description of the Transmit Status is the same as for bits [23:0] in TDES0. If IEEE 1588 time stamping is enabled, a specific frames' 64-bit time stamp is returned, along with the transmit status.

### Transmit checksum offload

Communication protocols such as TCP and UDP implement checksum fields, which helps determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the Ethernet controller has a transmit checksum offload feature that supports checksum calculation and insertion in the transmit path, and error detection in the receive path. This section explains the operation of the checksum offload feature for transmitted frames.

*Note: The checksum for TCP, UDP or ICMP is calculated over a complete frame, then inserted into its corresponding header field. Due to this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-forward mode (that is, when the TSF bit is set in the ETH\_ETH\_DMAOMR register). If the core is configured for Threshold (cut-through) mode, the Transmit checksum offload is bypassed.*

*You must make sure the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the MAC Core transmitter. If the FIFO depth is less than the input Ethernet frame size, the payload (TCP/UDP/ICMP) checksum insertion function is bypassed and only the frame's IPv4 Header checksum is modified, even in Store-and-forward mode.*

The transmit checksum offload supports two types of checksum calculation and insertion. This checksum can be controlled for each frame by setting the CIC bits (Bits 27:23 in TDES0, described in [TDES0: Transmit descriptor Word0](#)).

See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460 and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6 and ICMPv6 packet header specifications, respectively.

- IP header checksum  
In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit header checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The checksum offload detects an IPv4 datagram when the Ethernet frame's Type field has the value 0x0800 and the IP datagram's Version field has the value 0x4. The input frame's checksum field is ignored during calculation and replaced by the calculated value. IPv6 headers do not have a checksum field; thus, the checksum offload does not modify IPv6 header fields. The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the

IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- a) For IPv4 datagrams:
    - The received Ethernet type is 0x0800, but the IP header's Version field does not equal 0x4
    - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes)
    - The total frame length is less than the value given in the IPv4 Header Length field
  - b) For IPv6 datagrams:
    - The Ethernet type is 0x86DD but the IP header Version field does not equal 0x6
    - The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) has been completely received. Even when the checksum offload detects such an IP header error, it inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.
- TCP/UDP/ICMP checksum

The TCP/UDP/ICMP checksum processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP or ICMP.

Note that:

- a) For non-TCP, -UDP, or -ICMP/ICMPv6 payloads, this checksum is bypassed and nothing further is modified in the frame.
- b) Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an authentication header or encapsulated security payload), and IPv6 frames with routing headers are bypassed and not processed by the checksum.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. It can work in the following two modes:

- In the first mode, the TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's checksum field. The checksum field is included in the checksum calculation, and then replaced by the final calculated checksum.
- In the second mode, the checksum field is ignored, the TCP, UDP, or ICMPv6 pseudo-header data are included into the checksum calculation, and the checksum field is overwritten with the final calculated value.

Note that: for ICMP-over-IPv4 packets, the checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the payload checksum error status bit in the Transmit Status vector (bit 12). The payload checksum error status bit is set when either of the following is detected:

- the frame has been forwarded to the MAC transmitter in Store-and-forward mode without the end of frame being written to the FIFO
- the packet ends before the number of bytes indicated by the payload length field in the IP header is received.

When the packet is longer than the indicated payload length, the bytes are ignored as stuff bytes, and no error is reported. When the first type of error is detected, the TCP,

UDP or ICMP header is not modified. For the second error type, still, the calculated checksum is inserted into the corresponding header field.

MII/RMII transmit bit order

Each nibble from the MII is transmitted on the RMII a dibit at a time with the order of dibit transmission shown in [Figure 362](#). Lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

### 33.5.3 MAC frame reception

The MAC received frames are pushed into the Rx FIFO. The status (fill level) of this FIFO is indicated to the DMA once it crosses the configured receive threshold (RTC in the ETH\_DMAOMR register) so that the DMA can initiate pre-configured burst transfers towards the AHB interface.

In the default Cut-through mode, when 64 bytes (configured with the RTC bits in the ETH\_DMAOMR register) or a full packet of data are received into the FIFO, the data are popped out and the DMA is notified of its availability. Once the DMA has initiated the transfer to the AHB interface, the data transfer continues from the FIFO until a complete

packet has been transferred. Upon completion of the EOF frame transfer, the status word is popped out and sent to the DMA controller.

In Rx FIFO Store-and-forward mode (configured by the RSF bit in the ETH\_DMAOMR register), a frame is read only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the core is configured to do so) such that only valid frames are read and forwarded to the application. In Cut-through mode, some error frames are not dropped, because the error status is received at the end of the frame, by which time the start of that frame has already been read of the FIFO.

A receive operation is initiated when the MAC detects an SFD on the MII. The core strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The frame is dropped in the core if it fails the address filter.

### Receive protocol

The received frame preamble and SFD are stripped. Once the SFD has been detected, the MAC starts sending the Ethernet frame data to the receive FIFO, beginning with the first byte following the SFD (destination address). If IEEE 1588 time stamping is enabled, a snapshot of the system time is taken when any frame's SFD is detected on the MII. Unless the MAC filters out and drops the frame, this time stamp is passed on to the application.

If the received frame length/type field is less than 0x600 and if the MAC is programmed for the auto CRC/pad stripping option, the MAC sends the data of the frame to Rx FIFO up to the count specified in the length/type field, then starts dropping bytes (including the FCS field). If the Length/Type field is greater than or equal to 0x600, the MAC sends all received Ethernet frame data to Rx FIFO, regardless of the value on the programmed auto-CRC strip option. The MAC watchdog timer is enabled by default, that is, frames above 2048 bytes (DA + SA + LT + Data + pad + FCS) are cut off. This feature can be disabled by programming the watchdog disable (WD) bit in the MAC configuration register. However, even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog timeout status is given.

### Receive CRC: automatic CRC and pad stripping

The MAC checks for any CRC error in the receiving frame. It calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field. The encoding is defined by the following polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Regardless of the auto-pad/CRC strip, the MAC receives the entire frame to compute the CRC check for the received frame.

### Receive checksum offload

Both IPv4 and IPv6 frames in the received Ethernet frames are detected and processed for data integrity. You can enable the receive checksum offload by setting the IPCO bit in the ETH\_MACCR register. The MAC receiver identifies IPv4 or IPv6 frames by checking for value 0x0800 or 0x86DD, respectively, in the received Ethernet frame Type field. This identification applies to VLAN-tagged frames as well. The receive checksum offload calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The IP Header Error bit is set for any mismatch between the indicated payload

type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header). The receive checksum offload also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP or ICMP specifications. It includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP or ICMP payload does not match the expected payload length given in the IP header. As mentioned in [TCP/UDP/ICMP checksum](#), the receive checksum offload bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP. This information (whether the checksum is bypassed or not) is given in the receive status, as described in the [RDES0: Receive descriptor Word0](#) section. In this configuration, the core does not append any payload checksum bytes to the received Ethernet frames.

As mentioned in [RDES0: Receive descriptor Word0](#), the meaning of certain register bits changes as shown in [Table 191](#).

**Table 191. Frame statuses**

| Bit 18:<br>Ethernet frame | Bit 27: Header<br>checksum error | Bit 28: Payload<br>checksum error | Frame status                                                                                                   |
|---------------------------|----------------------------------|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| 0                         | 0                                | 0                                 | The frame is an IEEE 802.3 frame (Length field value is less than 0x0600).                                     |
| 1                         | 0                                | 0                                 | IPv4/IPv6 Type frame in which no checksum error is detected.                                                   |
| 1                         | 0                                | 1                                 | IPv4/IPv6 Type frame in which a payload checksum error (as described for PCE) is detected                      |
| 1                         | 1                                | 0                                 | IPv4/IPv6 Type frame in which IP header checksum error (as described for IPCO HCE) is detected.                |
| 1                         | 1                                | 1                                 | IPv4/IPv6 Type frame in which both PCE and IPCO HCE are detected.                                              |
| 0                         | 0                                | 1                                 | IPv4/IPv6 Type frame in which there is no IP HCE and the payload check is bypassed due to unsupported payload. |
| 0                         | 1                                | 1                                 | Type frame which is neither IPv4 or IPv6 (checksum offload bypasses the checksum check completely)             |
| 0                         | 1                                | 0                                 | Reserved                                                                                                       |

### Receive frame controller

If the RA bit is reset in the MAC CSR frame filter register, the MAC performs frame filtering based on the destination/source address (the application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc.). On detecting a filter-fail, the frame is dropped and not transferred to the application. When the filtering parameters are changed dynamically, and in case of (DA-SA) filter-fail, the rest of the frame is dropped and the Rx Status Word is immediately updated (with zero frame

length, CRC error and Runt Error bits set), indicating the filter fail. In Ethernet power down mode, all received frames are dropped, and are not forwarded to the application.

### Receive flow control

The MAC detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame (only in Full-duplex mode). The Pause frame detection function can be enabled or disabled with the RFCE bit in ETH\_MACFCR. Once receive flow control has been enabled, the received frame destination address begins to be monitored for any match with the multicast address of the control frame (0x0180 C200 0001). If a match is detected (the destination address of the received frame matches the reserved control frame destination address), the MAC then decides whether or not to transfer the received control frame to the application, based on the level of the PCF bit in ETH\_MACFFR.

The MAC also decodes the type, opcode, and Pause Timer fields of the receiving control frame. If the byte count of the status indicates 64 bytes, and if there is no CRC error, the MAC transmitter pauses the transmission of any data frame for the duration of the decoded Pause time value, multiplied by the slot time (64 byte times for both 10/100 Mbit/s modes). Meanwhile, if another Pause frame is detected with a zero Pause time value, the MAC resets the Pause time and manages this new pause request.

If the received control frame matches neither the type field (0x8808), the opcode (0x00001), nor the byte length (64 bytes), or if there is a CRC error, the MAC does not generate a Pause.

In the case of a pause frame with a multicast destination address, the MAC filters the frame based on the address match.

For a pause frame with a unicast destination address, the MAC filtering depends on whether the DA matched the contents of the MAC address 0 register and whether the UPDF bit in ETH\_MACFCR is set (detecting a pause frame even with a unicast destination address). The PCF register bits (bits [7:6] in ETH\_MACFFR) control filtering for control frames in addition to address filtering.

### Receive operation multiframe handling

Since the status is available immediately following the data, the FIFO is capable of storing any number of frames into it, as long as it is not full.

### Error handling

If the Rx FIFO is full before it receives the EOF data from the MAC, an overflow is declared and the whole frame is dropped, and the overflow counter in the (ETH\_DMAMFBOCR register) is incremented. The status indicates a partial frame due to overflow. The Rx FIFO can filter error and undersized frames, if enabled (using the FEF and FUGF bits in ETH\_DMAOMR).

If the Receive FIFO is configured to operate in Store-and-forward mode, all error frames can be filtered and dropped.

In Cut-through mode, if a frame's status and length are available when that frame's SOF is read from the Rx FIFO, then the complete erroneous frame can be dropped. The DMA can flush the error frame being read from the FIFO, by enabling the receive frame flash bit. The data transfer to the application (DMA) is then stopped and the rest of the frame is internally read and dropped. The next frame transfer can then be started, if available.

### Receive status word

At the end of the Ethernet frame reception, the MAC outputs the receive status to the application (DMA). The detailed description of the receive status is the same as for bits[31:0] in RDES0, given in [RDES0: Receive descriptor Word0](#).

### Frame length interface

In case of switch applications, data transmission and reception between the application and MAC happen as complete frame transfers. The application layer should be aware of the length of the frames received from the ingress port in order to transfer the frame to the egress port. The MAC core provides the frame length of each received frame inside the status at the end of each frame reception.

*Note:* A frame length value of 0 is given for partial frames written into the Rx FIFO due to overflow.

### MII/RMII receive bit order

Each nibble is transmitted to the MII from the dibit received from the RMII in the nibble transmission order shown in [Figure 366](#). The lower-order bits (D0 and D1) are received first, followed by the higher-order bits (D2 and D3).

ai15636

### 33.5.4 MAC interrupts

Interrupts can be generated from the MAC core as a result of various events.

The ETH\_MACSR register describes the events that can cause an interrupt from the MAC core. You can prevent each event from asserting the interrupt by setting the corresponding mask bits in the Interrupt Mask register.

The interrupt register bits only indicate the block from which the event is reported. You have to read the corresponding status registers and other registers to clear the interrupt. For example, bit 3 of the Interrupt register, set high, indicates that the Magic packet or Wake-on-LAN frame is received in Power-down mode. You must read the ETH\_MACPMTCSR register to clear this interrupt event.

**Figure 370. MAC core interrupt masking scheme**

### 33.5.5 MAC filtering

#### Address filtering

Address filtering checks the destination and source addresses on all received frames and the address filtering status is reported accordingly. Address checking is based on different parameters (Frame filter register) chosen by the application. The filtered frame can also be identified: multicast or broadcast frame.

Address filtering uses the station's physical (MAC) address and the Multicast Hash table for address checking purposes.

#### Unicast destination address filter

The MAC supports up to 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HU bit in the Frame filter register is reset), the MAC compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr3 are selected with an individual enable bit. Each byte of these other addresses (MacAddr1–MacAddr3) can be masked during comparison with the corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This helps group address filtering for the DA. In Hash filtering mode (when HU bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the 6 upper CRC (see note 1 below) bits of the received destination address to index the content of the Hash table. A value of 000000 selects bit 0 in the selected register, and a value of 111111 selects bit 63 in the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

*Note:* This CRC is a 32-bit value coded by the following polynomial (for more details refer to [Section 33.5.3](#)):

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

### Multicast destination address filter

The MAC can be programmed to pass all multicast frames by setting the PAM bit in the Frame filter register. If the PAM bit is reset, the MAC performs the filtering for multicast addresses based on the HM bit in the Frame filter register. In Perfect filtering mode, the multicast address is compared with the programmed MAC destination address registers (1–3). Group address filtering is also supported. In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. For hash filtering, the MAC uses the 6 upper CRC (see note 1 below) bits of the received multicast address to index the content of the Hash table. A value of 000000 selects bit 0 in the selected register and a value of 111111 selects bit 63 in the Hash Table register. If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

*Note:* This CRC is a 32-bit value coded by the following polynomial (for more details refer to [Section 33.5.3](#)):

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

### Hash or perfect address filter

The DA filter can be configured to pass a frame when its DA matches either the Hash filter or the Perfect filter by setting the HPF bit in the Frame filter register and setting the corresponding HU or HM bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.

### Broadcast address filter

The MAC does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames by setting the BFD bit in the Frame filter register, any broadcast frames are dropped.

### Unicast source address filter

The MAC can also perform perfect filtering based on the source address field of the received frames. By default, the MAC compares the SA field with the values programmed in the SA registers. The MAC address registers [1:3] can be configured to contain SA instead of DA for comparison, by setting bit 30 in the corresponding register. Group filtering with SA is also supported. The frames that fail the SA filter are dropped by the MAC if the SAF bit in the Frame filter register is set. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word (see [RDES0: Receive descriptor Word0](#)).

When the SAF bit is set, the result of the SA and DA filters is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result drops the frame. Both filters have to pass the frame for the frame to be forwarded to the application.

### Inverse filtering operation

For both destination and source address filtering, there is an option to invert the filter-match result at the final output. These are controlled by the DAIF and SAIF bits in the Frame filter register, respectively. The DAIF bit is applicable for both Unicast and Multicast DA frames. The result of the unicast/multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of the unicast SA filter is inverted. [Table 192](#)

and [Table 193](#) summarize destination and source address filtering based on the type of frame received.

**Table 192. Destination address filtering**

| Frame type | PM | HPF | HU | DAIF | HM | PAM | DB | DA filter operation                                                                  |
|------------|----|-----|----|------|----|-----|----|--------------------------------------------------------------------------------------|
| Broadcast  | 1  | X   | X  | X    | X  | X   | X  | Pass                                                                                 |
|            | 0  | X   | X  | X    | X  | X   | 0  | Pass                                                                                 |
|            | 0  | X   | X  | X    | X  | X   | 1  | Fail                                                                                 |
| Unicast    | 1  | X   | X  | X    | X  | X   | X  | Pass all frames                                                                      |
|            | 0  | X   | 0  | 0    | X  | X   | X  | Pass on perfect/group filter match                                                   |
|            | 0  | X   | 0  | 1    | X  | X   | X  | Fail on perfect/Group filter match                                                   |
|            | 0  | 0   | 1  | 0    | X  | X   | X  | Pass on hash filter match                                                            |
|            | 0  | 0   | 1  | 1    | X  | X   | X  | Fail on hash filter match                                                            |
|            | 0  | 1   | 1  | 0    | X  | X   | X  | Pass on hash or perfect/Group filter match                                           |
|            | 0  | 1   | 1  | 1    | X  | X   | X  | Fail on hash or perfect/Group filter match                                           |
| Multicast  | 1  | X   | X  | X    | X  | X   | X  | Pass all frames                                                                      |
|            | X  | X   | X  | X    | X  | 1   | X  | Pass all frames                                                                      |
|            | 0  | X   | X  | 0    | 0  | 0   | X  | Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x         |
|            | 0  | 0   | X  | 0    | 1  | 0   | X  | Pass on hash filter match and drop PAUSE control frames if PCF = 0x                  |
|            | 0  | 1   | X  | 0    | 1  | 0   | X  | Pass on hash or perfect/Group filter match and drop PAUSE control frames if PCF = 0x |
|            | 0  | X   | X  | 1    | 0  | 0   | X  | Fail on perfect/Group filter match and drop PAUSE control frames if PCF = 0x         |
|            | 0  | 0   | X  | 1    | 1  | 0   | X  | Fail on hash filter match and drop PAUSE control frames if PCF = 0x                  |
|            | 0  | 1   | X  | 1    | 1  | 0   | X  | Fail on hash or perfect/Group filter match and drop PAUSE control frames if PCF = 0x |

Table 193. Source address filtering

| Frame type | PM | SAIF | SAF | SA filter operation                                                        |
|------------|----|------|-----|----------------------------------------------------------------------------|
| Unicast    | 1  | X    | X   | Pass all frames                                                            |
|            | 0  | 0    | 0   | Pass status on perfect/Group filter match but do not drop frames that fail |
|            | 0  | 1    | 0   | Fail status on perfect/group filter match but do not drop frame            |
|            | 0  | 0    | 1   | Pass on perfect/group filter match and drop frames that fail               |
|            | 0  | 1    | 1   | Fail on perfect/group filter match and drop frames that fail               |

### 33.5.6 MAC loopback mode

The MAC supports loopback of transmitted frames onto its receiver. By default, the MAC loopback function is disabled, but this feature can be enabled by programming the Loopback bit in the MAC ETH\_MACCR register.

### 33.5.7 MAC management counters: MMC

The MAC management counters (MMC) maintain a set of registers for gathering statistics on the received and transmitted frames. These include a control register for controlling the behavior of the registers, two 32-bit registers containing generated interrupts (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the application. Each register is 32 bits wide.

[Section 33.8](#) describes the various counters and lists the addresses of each of the statistics counters. This address is used for read/write accesses to the desired transmit/receive counter.

The Receive MMC counters are updated for frames that pass address filtering. Dropped frames statistics are not updated unless the dropped frames are runt frames of less than 6 bytes (DA bytes are not received fully).

#### Good transmitted and received frames

Transmitted frames are considered “good” if transmitted successfully. In other words, a transmitted frame is good if the frame transmission is not aborted due to any of the following errors:

- + Jabber Timeout
- + No Carrier/Loss of Carrier
- + Late Collision
- + Frame Underflow
- + Excessive Deferral
- + Excessive Collision

Received frames are considered “good” if none of the following errors exists:

- + CRC error
- + Runt Frame (shorter than 64 bytes)
- + Alignment error (in 10/ 100 Mbit/s only)
- + Length error (non-Type frames only)
- + Out of Range (non-Type frames only, longer than maximum size)
- + MII\_RXER Input error

The maximum frame size depends on the frame type, as follows:

- + Untagged frame maxsize = 1518
- + VLAN Frame maxsize = 1522

### 33.5.8 Power management: PMT

This section describes the power management (PMT) mechanisms supported by the MAC. PMT supports the reception of network (remote) wake-up frames and Magic Packet frames. PMT generates interrupts for wake-up frames and Magic Packets received by the MAC. The PMT block is enabled with remote wake-up frame enable and Magic Packet enable. These enable bits (WFE and MPE) are in the ETH\_MACPMTCSR register and are programmed by the application. When the power down mode is enabled in the PMT, then all received frames are dropped by the MAC and they are not forwarded to the application. The MAC comes out of the power down mode only when either a Magic Packet or a Remote wake-up frame is received and the corresponding detection is enabled.

#### Remote wake-up frame filter register

There are eight wake-up frame filter registers. To write on each of them, load the wake-up frame filter register value by value. The wanted values of the wake-up frame filter are loaded by sequentially loading eight times the wake-up frame filter register. The read operation is identical to the write operation. To read the eight values, you have to read eight times the wake-up frame filter register to reach the last register. Each read/write points the wake-up frame filter register to the next filter register.

**Figure 371. Wake-up frame filter register**

|                          |                    |                  |                 |                  |                   |                  |                 |                  |
|--------------------------|--------------------|------------------|-----------------|------------------|-------------------|------------------|-----------------|------------------|
| Wakeup frame filter reg0 | Filter 0 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg1 | Filter 1 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg2 | Filter 2 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg3 | Filter 3 Byte Mask |                  |                 |                  |                   |                  |                 |                  |
| Wakeup frame filter reg4 | RSVD               | Filter 3 Command | RSVD            | Filter 2 Command | RSVD              | Filter 1 Command | RSVD            | Filter 0 Command |
| Wakeup frame filter reg5 | Filter 3 Offset    |                  | Filter 2 Offset |                  | Filter 1 Offset   |                  | Filter 0 Offset |                  |
| Wakeup frame filter reg6 | Filter 1 CRC - 16  |                  |                 |                  | Filter 0 CRC - 16 |                  |                 |                  |
| Wakeup frame filter reg7 | Filter 3 CRC - 16  |                  |                 |                  | Filter 2 CRC - 16 |                  |                 |                  |

ai15647

ai15647

- **Filter i Byte Mask**  
This register defines which bytes of the frame are examined by filter i (0, 1, 2, and 3) in order to determine whether or not the frame is a wake-up frame. The MSB (thirty-first bit) must be zero. Bit j [30:0] is the Byte Mask. If bit j (byte number) of the Byte Mask is set, then Filter i Offset + j of the incoming frame is processed by the CRC block; otherwise Filter i Offset + j is ignored.
- **Filter i Command**  
This 4-bit command controls the filter i operation. Bit 3 specifies the address type, defining the pattern's destination address type. When the bit is set, the pattern applies to only multicast frames. When the bit is reset, the pattern applies only to unicast frames. Bit 2 and bit 1 are reserved. Bit 0 is the enable bit for filter i; if bit 0 is not set, filter i is disabled.
- **Filter i Offset**  
This register defines the offset (within the frame) from which the frames are examined by filter i. This 8-bit pattern offset is the offset for the filter i first byte to be examined. The minimum allowed is 12, which refers to the 13th byte of the frame (offset value 0 refers to the first byte of the frame).
- **Filter i CRC-16**  
This register contains the CRC\_16 value calculated from the pattern, as well as the byte mask programmed to the wake-up filter register block.

### Remote wake-up frame detection

When the MAC is in sleep mode and the remote wake-up bit is enabled in the ETH\_MACPMTCSR register, normal operation is resumed after receiving a remote wake-up frame. The application writes all eight wake-up filter registers, by performing a sequential write to the wake-up frame filter register address. The application enables remote wake-up by writing a 1 to bit 2 in the ETH\_MACPMTCSR register. PMT supports four programmable filters that provide different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received. Filter\_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter Byte Mask determines which bytes of the frame must be examined. The thirty-first bit of Byte Mask must be set to zero. The wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the ETH\_MACPMTCSR register for every remote wake-up frame received. If enabled, a PMT interrupt is generated to indicate the reception of a remote wake-up frame.

### Magic packet detection

The Magic Packet frame is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a Magic Packet, addressed to the node on the network. Only Magic Packets that are addressed to the device or a broadcast address are checked to determine whether they meet the wake-up requirements. Magic Packets that pass address filtering (unicast or broadcast) are checked to determine whether they meet the remote Wake-on-LAN data format of 6 bytes of all ones followed by a MAC address appearing 16 times. The application enables Magic Packet wake-up by writing a 1 to bit 1 in the ETH\_MACPMTCSR register. The PMT block constantly monitors each frame addressed to

the node for a specific Magic Packet pattern. Each received frame is checked for a 0xFFFF FFFF FFFF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 0xFFFF FFFF FFFF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (0xFFFF FFFF FFFF). The device also accepts a multicast frame, as long as the 16 duplications of the MAC address are detected. If the MAC address of a node is 0x0011 2233 4455, then the MAC scans for the data sequence:

```
Destination address source address ..... FFFF FFFF FFFF
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
0011 2233 4455 0011 2233 4455 0011 2233 4455 0011 2233 4455
...CRC
```

Magic Packet detection is updated in the ETH\_MACPMTCSR register for received Magic Packet. If enabled, a PMT interrupt is generated to indicate the reception of a Magic Packet.

### System consideration during power-down

The Ethernet PMT block is able to detect frames while the system is in the Stop mode, provided that the EXTI line 19 is enabled.

The MAC receiver state machine should remain enabled during the power-down mode. This means that the RE bit has to remain set in the ETH\_MACCR register because it is involved in magic packet/ wake-on-LAN frame detection. The transmit state machine should however be turned off during the power-down mode by clearing the TE bit in the ETH\_MACCR register. Moreover, the Ethernet DMA should be disabled during the power-down mode, because it is not necessary to copy the magic packet/wake-on-LAN frame into the SRAM. To disable the Ethernet DMA, clear the ST bit and the SR bit (for the transmit DMA and the receive DMA, respectively) in the ETH\_DMAOMR register.

The recommended power-down and wake-up sequences are as follows:

1. Disable the transmit DMA and wait for any previous frame transmissions to complete. These transmissions can be detected when the transmit interrupt ETH\_DMASR register[0] is received.
2. Disable the MAC transmitter and MAC receiver by clearing the RE and TE bits in the ETH\_MACCCR configuration register.
3. Wait for the receive DMA to have emptied all the frames in the Rx FIFO.
4. Disable the receive DMA.
5. Configure and enable the EXTI line 19 to generate either an event or an interrupt.
6. If you configure the EXTI line 19 to generate an interrupt, you also have to correctly configure the ETH\_WKUP\_IRQ Handler function, which should clear the pending bit of the EXTI line 19.
7. Enable Magic packet/Wake-on-LAN frame detection by setting the MFE/ WFE bit in the ETH\_MACPMTCSR register.
8. Enable the MAC power-down mode, by setting the PD bit in the ETH\_MACPMTCSR register.
9. Enable the MAC Receiver by setting the RE bit in the ETH\_MACCCR register.
10. Enter the system's Stop mode (for more details refer to [Section 4.3.4: Stop mode](#)):
11. On receiving a valid wake-up frame, the Ethernet peripheral exits the power-down mode.
12. Read the ETH\_MACPMTCSR to clear the power management event flag, enable the MAC transmitter state machine, and the receive and transmit DMA.
13. Configure the system clock: enable the HSE and set the clocks.

### 33.5.9 Precision time protocol (IEEE1588 PTP)

The IEEE 1588 standard defines a protocol that allows precise clock synchronization in measurement and control systems implemented with technologies such as network communication, local computing and distributed objects. The protocol applies to systems that communicate by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol is used to synchronize heterogeneous systems that include clocks of varying inherent precision, resolution and stability. The protocol supports system-wide synchronization accuracy in the submicrosecond range with minimum network and local clock computing resources. The message-based protocol, known as the precision time protocol (PTP), is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. The protocol's technique for synchronizing a slave node to a master node by exchanging PTP messages is described in [Figure 372](#).

Figure 372. Networked time synchronization

1. The master broadcasts PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is  $t_1$ . For Ethernet ports, this time has to be captured at the MII.
2. A slave receives the Sync message and also captures the exact time,  $t_2$ , using its timing reference.
3. The master then sends the slave a Follow\_up message, which contains the  $t_1$  information for later use.
4. The slave sends the master a Delay\_Req message, noting the exact time,  $t_3$ , at which this frame leaves the MII.
5. The master receives this message and captures the exact time,  $t_4$ , at which it enters its system.
6. The master sends the  $t_4$  information to the slave in the Delay\_Resp message.
7. The slave uses the four values of  $t_1$ ,  $t_2$ ,  $t_3$ , and  $t_4$  to synchronize its local timing reference to the master's timing reference.

Most of the protocol implementation occurs in the software, above the UDP layer. As described above, however, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII. This timing information has to be captured and returned to the software for a proper, high-accuracy implementation of PTP.

### Reference timing source

To get a snapshot of the time, the core requires a reference time in 64-bit format (split into two 32-bit channels, with the upper 32 bits providing time in seconds, and the lower 32 bits indicating time in nanoseconds) as defined in the IEEE 1588 specification.

The PTP reference clock input is used to internally generate the reference time (also called the System Time) and to capture time stamps. The frequency of this reference clock must

be greater than or equal to the resolution of time stamp counter. The synchronization accuracy target between the master node and the slaves is around 100 ns.

The generation, update and modification of the System Time are described in [System Time correction methods](#).

The accuracy depends on the PTP reference clock input period, the characteristics of the oscillator (drift) and the frequency of the synchronization procedure.

Due to the synchronization from the Tx and Rx clock input domain to the PTP reference clock domain, the uncertainty on the time stamp latched value is 1 reference clock period. If we add the uncertainty due to resolution, we add half the period for time stamping.

### Transmission of frames with the PTP feature

When a frame's SFD is output on the MII, a time stamp is captured. Frames for which time stamp capture is required are controllable on a per-frame basis. In other words, each transmitted frame can be marked to indicate whether a time stamp must be captured or not for that frame. The transmitted frames are not processed to identify PTP frames. Frame control is exercised through the control bits in the transmit descriptor. Captured time stamps are returned to the application in the same way as the status is provided for frames. The time stamp is sent back along with the Transmit status of the frame, inside the corresponding transmit descriptor, thus connecting the time stamp automatically to the specific PTP frame. The 64-bit time stamp information is written back to the TDES2 and TDES3 fields, with TDES2 holding the time stamp's 32 least significant bits.

### Reception of frames with the PTP feature

When the IEEE 1588 time stamping feature is enabled, the Ethernet MAC captures the time stamp of all frames received on the MII. The MAC provides the time stamp as soon as the frame reception is complete. Captured time stamps are returned to the application in the same way as the frame status is provided. The time stamp is sent back along with the Receive status of the frame, inside the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES2 and RDES3 fields, with RDES2 holding the time stamp's 32 least significant bits.

### System Time correction methods

The 64-bit PTP time is updated using the PTP input reference clock, HCLK. This PTP time is used as a source to take snapshots (time stamps) of the Ethernet frames being transmitted or received at the MII. The System Time counter can be initialized or corrected using either the Coarse or the Fine correction method.

In the Coarse correction method, the initial value or the offset value is written to the Time stamp update register (refer to [Section 33.8.3](#)). For initialization, the System Time counter is written with the value in the Time stamp update registers, whereas for system time correction, the offset value (Time stamp update register) is added to or subtracted from the system time.

In the Fine correction method, the slave clock (reference clock) frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time, unlike in the Coarse correction method where it is corrected in a single clock cycle. The longer correction time helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register as shown in [Figure 373](#). The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter.

The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider. [Figure 373](#) shows this algorithm.

**Figure 373. System time update using the Fine correction method**

The system time update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (HCLK) is, let us say, 66 MHz, the ratio is calculated as  $66 \text{ MHz} / 50 \text{ MHz} = 1.32$ . Hence, the default addend value to be set in the register is  $2^{32} / 1.32$ , which is equal to 0xC1F0 7C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is  $65 / 50$  or 1.3 and the value to set in the addend register is  $2^{32} / 1.30$  equal to 0xC4EC 4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0 B7672. When the clock drift is zero, the default addend value of 0xC1F0 7C1F ( $2^{32} / 1.32$ ) should be programmed.

In [Figure 373](#), the constant value used to increment the subsecond register is 0d43. This makes an accuracy of 20 ns in the system time (in other words, it is incremented by 20 ns steps).

The software has to calculate the drift in frequency based on the Sync messages, and to update the Addend register accordingly. Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue0} = 2^{32} / \text{FreqDivisionRatio}$$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm described below must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time MasterSyncTime (n) the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTime (n) and computes MasterClockTime (n) as:  

$$\text{MasterClockTime (n)} = \text{MasterSyncTime (n)} + \text{MasterToSlaveDelay (n)}$$
- The master clock count for current Sync cycle, MasterClockCount (n) is given by:  

$$\text{MasterClockCount (n)} = \text{MasterClockTime (n)} - \text{MasterClockTime (n - 1)}$$
 (assuming that MasterToSlaveDelay is the same for Sync cycles n and n - 1)
- The slave clock count for current Sync cycle, SlaveClockCount (n) is given by:  

$$\text{SlaveClockCount (n)} = \text{SlaveClockTime (n)} - \text{SlaveClockTime (n - 1)}$$
- The difference between master and slave clock counts for current Sync cycle, ClockDiffCount (n) is given by:  

$$\text{ClockDiffCount (n)} = \text{MasterClockCount (n)} - \text{SlaveClockCount (n)}$$
- The frequency-scaling factor for slave clock, FreqScaleFactor (n) is given by:  

$$\text{FreqScaleFactor (n)} = (\text{MasterClockCount (n)} + \text{ClockDiffCount (n)}) / \text{SlaveClockCount (n)}$$
- The frequency compensation value for Addend register, FreqCompensationValue (n) is given by:  

$$\text{FreqCompensationValue (n)} = \text{FreqScaleFactor (n)} \times \text{FreqCompensationValue (n - 1)}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, due to changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.

### Programming steps for system time generation initialization

The time stamping feature can be enabled by setting bit 0 in the Time stamp control register (ETH\_PTPTSCR). However, it is essential to initialize the time stamp counter after this bit is set to start time stamp operation. The proper sequence is the following:

1. Mask the Time stamp trigger interrupt by setting bit 9 in the MACIMR register.
2. Program Time stamp register bit 0 to enable time stamping.
3. Program the Subsecond increment register based on the PTP clock frequency.
4. If you are using the Fine correction method, program the Time stamp addend register and set Time stamp control register bit 5 (addend register update).
5. Poll the Time stamp control register until bit 5 is cleared.
6. To select the Fine correction method (if required), program Time stamp control register bit 1.
7. Program the Time stamp high update and Time stamp low update registers with the appropriate time value.
8. Set Time stamp control register bit 2 (Time stamp init).
9. The Time stamp counter starts operation as soon as it is initialized with the value written in the Time stamp update register.
10. Enable the MAC receiver and transmitter for proper time stamping.

**Note:** *If time stamp operation is disabled by clearing bit 0 in the ETH\_PTPTSCR register, the above steps must be repeated to restart the time stamp operation.*

### Programming steps for system time update in the Coarse correction method

To synchronize or update the system time in one process (coarse correction method), perform the following steps:

1. Write the offset (positive or negative) in the Time stamp update high and low registers.
2. Set bit 3 (TSSTU) in the Time stamp control register.
3. The value in the Time stamp update registers is added to or subtracted from the system time when the TSSTU bit is cleared.

### Programming steps for system time update in the Fine correction method

To synchronize or update the system time to reduce system-time jitter (fine correction method), perform the following steps:

1. With the help of the algorithm explained in [System Time correction methods](#), calculate the rate by which you want to speed up or slow down the system time increments.
2. Update the time stamp.
3. Wait the time you want the new value of the Addend register to be active. You can do this by activating the Time stamp trigger interrupt after the system time reaches the target value.
4. Program the required target time in the Target time high and low registers. Unmask the Time stamp interrupt by clearing bit 9 in the ETH\_MACIMR register.
5. Set Time stamp control register bit 4 (TSARU).
6. When this trigger causes an interrupt, read the ETH\_MACCSR register.
7. Reprogram the Time stamp addend register with the old value and set ETH\_TPTSCR bit 5 again.

### PTP trigger internal connection with TIM2

The MAC provides a trigger interrupt when the system time becomes greater than the target time. Using an interrupt introduces a known latency plus an uncertainty in the command execution time.

In order to avoid this uncertainty, a PTP trigger output signal is set high when the system time is greater than the target time. It is internally connected to the TIM2 input trigger. With this signal, the input capture feature, the output compare feature and the waveforms of the timer can be used, triggered by the synchronized PTP system time. No uncertainty is introduced since the clock of the timer (PCLK1: TIM2 APB1 clock) and PTP reference clock (HCLK) are synchronous.

This PTP trigger signal is connected to the TIM2 ITR1 input selectable by software. The connection is enabled through bits 11 and 10 in the TIM2 option register (TIM2\_OR).

[Figure 374](#) shows the connection.

**Figure 374. PTP trigger output to TIM2 ITR1 connection**

### PTP pulse-per-second output signal

This PTP pulse output is used to check the synchronization between all nodes in the network. To be able to test the difference between the local slave clock and the master reference clock, both clocks were given a pulse-per-second (PPS) output signal that may be connected to an oscilloscope if necessary. The deviation between the two signals can therefore be measured. The pulse width of the PPS output is 125 ms.

The PPS output is enabled through a GPIO alternate function. (GPIO\_AFR register).

The default frequency of the PPS output is 1 Hz. PPSFREQ[3:0] (in ETH\_PTPPPSCR) can be used to set the frequency of the PPS output to  $2^{\text{PPSFREQ}}$  Hz.

When set to 1 Hz, the PPS pulse width is 125 ms with binary rollover (TSSSR=0, bit 9 in ETH\_PTPTSCR) and 100 ms with digital rollover (TSSSR=1). When set to 2 Hz and higher, the duty cycle of the PPS output is 50% with binary rollover.

With digital rollover (TSSSR=1), it is recommended not to use the PPS output with a frequency other than 1 Hz as it would have irregular waveforms (though its average frequency would always be correct during any one-second window).

**Figure 375. PPS output**

## 33.6 Ethernet functional description: DMA controller operation

The DMA has independent transmit and receive engines, and a CSR space. The transmit engine transfers data from system memory into the Tx FIFO while the receive engine transfers data from the Rx FIFO into system memory. The controller utilizes descriptors to efficiently move data from source to destination with minimum CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the CPU in cases such as frame transmit and receive transfer completion, and other normal/error conditions. The DMA and the STM32F4xx communicate through two data structures:

- Control and status registers (CSR)
- Descriptor lists and data buffers.

Control and status registers are described in detail in [Section 33.8](#). Descriptors are described in detail in [Normal Tx DMA descriptors](#).

The DMA transfers the received data frames to the receive buffer in the STM32F4xx memory, and transmits data frames from the transmit buffer in the STM32F4xx memory. Descriptors that reside in the STM32F4xx memory act as pointers to these buffers. There are two descriptor lists: one for reception, and one for transmission. The base address of each list is written into DMA registers 3 and 4, respectively. A descriptor list is forward-linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by configuring the second address chained in both the receive and transmit descriptors (RDES1[14] and TDES0[20]). The descriptor lists reside in the Host's physical memory space. Each descriptor can point to a maximum of two buffers. This enables the use of two physically addressed buffers,

instead of two contiguous buffers in memory. A data buffer resides in the Host's physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end of frame is detected. Data chaining can be enabled or disabled. The descriptor ring and chain structure is shown in [Figure 376](#).

**Figure 376. Descriptor ring and chain structure**

### 33.6.1 Initialization of a transfer using DMA

Initialization for the MAC is as follows:

1. Write to ETH\_DMABMR to set STM32F4xx bus access parameters.
2. Write to the ETH\_DMAIER register to mask unnecessary interrupt causes.
3. The software driver creates the transmit and receive descriptor lists. Then it writes to both the ETH\_DMARDLAR and ETH\_DMATDLAR registers, providing the DMA with the start address of each list.
4. Write to MAC registers 1, 2, and 3 to choose the desired filtering options.
5. Write to the MAC ETH\_MACCR register to configure and enable the transmit and receive operating modes. The PS and DM bits are set based on the auto-negotiation result (read from the PHY).
6. Write to the ETH\_DMAOMR register to set bits 13 and 1 and start transmission and reception.
7. The transmit and receive engines enter the running state and attempt to acquire descriptors from the respective descriptor lists. The receive and transmit engines then begin processing receive and transmit operations. The transmit and receive processes are independent of each other and can be started or stopped separately.

### 33.6.2 Host bus burst access

The DMA attempts to execute fixed-length burst transfers on the AHB master interface if configured to do so (FB bit in ETH\_DMABMR). The maximum burst length is indicated and limited by the PBL field (ETH\_DMABMR [13:8]). The receive and transmit descriptors are

always accessed in the maximum possible burst size (limited by PBL) for the 16 bytes to be read.

The Transmit DMA initiates a data transfer only when there is sufficient space in the Transmit FIFO to accommodate the configured burst or the number of bytes until the end of frame (when it is less than the configured burst length). The DMA indicates the start address and the number of transfers required to the AHB Master Interface. When the AHB Interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4, INCR8, INCR16 and SINGLE transactions. Otherwise (no fixed-length burst), it transfers data using INCR (undefined length) and SINGLE transactions.

The Receive DMA initiates a data transfer only when sufficient data for the configured burst is available in Receive FIFO or when the end of frame (when it is less than the configured burst length) is detected in the Receive FIFO. The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4, INCR8, INCR16 and SINGLE transactions. If the end of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed in order to complete the fixed-length burst. Otherwise (FB bit in ETH\_DMABMR is reset), it transfers data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16), because the AHB interface does not support more than INCR16.

### 33.6.3 Host data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. In our system with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

- Example of buffer read:  
If the Transmit buffer address is 0x0000 0FF2, and 15 bytes need to be transferred, then the DMA reads five full words from address 0x0000 0FF0, but when transferring data to the Transmit FIFO, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures it transfers a full 32-bit data items to the Transmit FIFO, unless it is the end of frame.
- Example of buffer write:  
If the Receive buffer address is 0x0000 0FF2, and 16 bytes of a received frame need to be transferred, then the DMA writes five full 32-bit data items from address 0x0000 0FF0. But the first 2 bytes of the first transfer and the last 2 bytes of the third transfer have dummy data.

### 33.6.4 Buffer size calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (xDES0) of the descriptors. The driver has to calculate the sizes. The transmit DMA transfers the exact number of bytes (indicated by buffer size field in TDES1) towards the MAC core. If a descriptor is marked as first (FS bit in TDES0 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is

marked as last (LS bit in TDES0), then the DMA marks the last transfer from that data buffer as the end of frame. The receive DMA transfers data to a buffer until the buffer is full or the end of frame is received. If a descriptor is not marked as last (LS bit in RDES0), then the buffer(s) that correspond to the descriptor are full and the amount of valid data in a buffer is accurately indicated by the buffer size field minus the data buffer pointer offset when the descriptor's FS bit is set. The offset is zero when the data buffer pointer is aligned to the databus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits in RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of next frame with a new descriptor.

*Note: Even when the start address of a receive buffer is not aligned to the system databus width the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1024 byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1022 bytes, even though the buffer size is programmed as 1024 bytes, due to the start address offset.*

### 33.6.5 DMA arbiter

The arbiter inside the DMA takes care of the arbitration between transmit and receive channel accesses to the AHB master interface. Two types of arbitrations are possible: round-robin, and fixed-priority. When round-robin arbitration is selected (DA bit in ETH\_DMABMR is reset), the arbiter allocates the databus in the ratio set by the PM bits in ETH\_DMABMR, when both transmit and receive DMAs request access simultaneously. When the DA bit is set, the receive DMA always gets priority over the transmit DMA for data access.

### 33.6.6 Error response to DMA

For any data transfer initiated by a DMA channel, if the slave replies with an error response, that DMA stops all operations and updates the error bits and the fatal bus error bit in the Status register (ETH\_DMASR register). That DMA controller can resume operation only after soft- or hard-resetting the peripheral and re-initializing the DMA.

### 33.6.7 Tx DMA configuration

#### TxDMA operation: default (non-OSF) mode

The transmit DMA engine in default mode proceeds as follows:

1. The user sets up the transmit descriptor (TDES0-TDES3) and sets the OWN bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data.
2. Once the ST bit (ETH\_DMAOMR register[13]) is set, the DMA enters the Run state.

3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the CPU, or if an error condition occurs, transmission is suspended and both the Transmit buffer Unavailable (ETH\_DMASR register[2]) and Normal Interrupt Summary (ETH\_DMASR register[16]) bits are set. The transmit engine proceeds to Step 9.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] is set), the DMA decodes the transmit data buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the STM32F4xx memory and transfers the data.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end of Ethernet frame data is transferred.
7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time stamp value is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the OWN bit is cleared during this step, the CPU now owns this descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3.
8. Transmit Interrupt (ETH\_DMASR register [0]) is set after completing the transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its last descriptor. The DMA engine then returns to Step 3.
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby returns to Step 3) when it receives a transmit poll demand, and the Underflow Interrupt Status bit is cleared.

*Figure 377* shows the TxDMA transmission flow in default mode.

Figure 377. TxDMA operation in Default mode

ai15639

### TxDMA operation: OSF mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first (if the OSF bit is set in ETH\_DMAOMR register[2]). As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information. In OSF mode, the Run-state transmit DMA operates according to the following sequence:

1. The DMA operates as described in steps 1–6 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step 7.
4. The DMA fetches the Transmit frame from the STM32F4xx memory and transfers the frame until the end of frame data are transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the transmission status and time stamp of the previous frame. When the status is available, the DMA writes the time stamp to TDES2 and TDES3, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES0, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the Transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step 7).
7. In Suspend mode, if a pending status and time stamp are received by the DMA, it writes the time stamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode.
8. The DMA can exit Suspend mode and enter the Run state (go to Step 1 or Step 2 depending on pending status) only after receiving a Transmit Poll demand (ETH\_DMATPDR register).

*Figure 378* shows the basic flowchart in OSF mode.

Figure 378. TxDMA operation in OSF mode

ai15640

### Transmit frame processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Len fields contain valid data. If the transmit descriptor indicates that the MAC core must disable CRC or pad insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. Frames can be data-chained and span over several buffers. Frames have to be delimited by the first descriptor (TDES0[28]) and the last descriptor (TDES0[29]). As the transmission starts, TDES0[28] has to be set in the first descriptor. When this occurs, the frame data are transferred from the memory buffer to the Transmit FIFO. Concurrently, if the last descriptor (TDES0[29]) of the current frame is cleared, the transmit process attempts to acquire the next descriptor. The transmit process expects TDES0[28] to be cleared in this descriptor. If TDES0[29] is cleared, it indicates an intermediary buffer. If TDES0[29] is set, it

indicates the last buffer of the frame. After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the transmit descriptor 0 (TDES0) word of the descriptor that has the last segment set in transmit descriptor 0 (TDES0[29]). At this time, if Interrupt on Completion (TDES0[30]) is set, Transmit Interrupt (in ETH\_DMASR register [0]) is set, the next descriptor is fetched, and the process repeats. Actual frame transmission begins after the Transmit FIFO has reached either a programmable transmit threshold (ETH\_DMAOMR register[16:14]), or a full frame is contained in the FIFO. There is also an option for the Store and forward mode (ETH\_DMAOMR register[21]). Descriptors are released (OWN bit TDES0[31] is cleared) when the DMA finishes transferring the frame.

### Transmit polling suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the CPU (TDES0[31]=0) and the Transmit buffer unavailable flag is set (ETH\_DMASR register[2]). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set. If the second condition occurs, both the Abnormal Interrupt Summary (in ETH\_DMASR register [15]) and Transmit Underflow bits (in ETH\_DMASR register[5]) are set, and the information is written to Transmit Descriptor 0, causing the suspension. If the DMA goes into Suspend state due to the first condition, then both the Normal Interrupt Summary (ETH\_DMASR register [16]) and Transmit Buffer Unavailable (ETH\_DMASR register[2]) bits are set. In both cases, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA. The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

### Normal Tx DMA descriptors

The normal transmit descriptor structure consists of four 32-bit words as shown in [Figure 379](#). The bit descriptions of TDES0, TDES1, TDES2 and TDES3 are given below.

Note that enhanced descriptors must be used if time stamping is activated (ETH\_PTPTSCR bit 0, TSE=1) or if IPv4 checksum offload is activated (ETH\_MACCCR bit 10, IPCO=1).

**Figure 379. Normal transmit descriptor**

- **TDES0: Transmit descriptor Word0**

The application software has to program the control bits [30:26]+[23:20] plus the OWN bit [31] during descriptor initialization. When the DMA updates the descriptor (or writes it back), it resets all the control bits plus the OWN bit, and reports only the status bits.

**Bit 31 OWN:** Own bit

When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the CPU. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set.

**Bit 30 IC:** Interrupt on completion

When set, this bit sets the Transmit Interrupt (ETH\_DMASR[0]) after the present frame has been transmitted.

**Bit 29 LS:** Last segment

When set, this bit indicates that the buffer contains the last segment of the frame.

**Bit 28 FS:** First segment

When set, this bit indicates that the buffer contains the first segment of a frame.

**Bit 27 DC:** Disable CRC

When this bit is set, the MAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set.

**Bit 26 DP:** Disable pad

When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set.

**Bit 25 TTSE:** Transmit time stamp enable

When TTSE is set and when TSE is set (ETH\_PTPTSCR bit 0), IEEE1588 hardware time stamping is activated for the transmit frame described by the descriptor. This field is only valid when the First segment control bit (TDES0[28]) is set.

**Bit 24** Reserved, must be kept at reset value.

**Bits 23:22 CIC:** Checksum insertion control

These bits control the checksum calculation and insertion. Bit encoding is as shown below:

00: Checksum Insertion disabled

01: Only IP header checksum calculation and insertion are enabled

10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware

11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.

**Bit 21 TER:** Transmit end of ring

When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.

**Bit 20 TCH:** Second address chained

When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].

Bits 19:18 Reserved, must be kept at reset value.

**Bit 17 TTSS:** Transmit time stamp status

This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last segment control bit (TDES0[29]) is set.

Note that when enhanced descriptors are enabled (EDFE=1 in ETH\_DMABMR), TTSS=1 indicates that TDES6 and TDES7 have the time stamp value.

**Bit 16 IHE:** IP header error

When set, this bit indicates that the MAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet length/type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5.

**Bit 15 ES:** Error summary

Indicates the logical OR of the following bits:

TDES0[14]: Jabber timeout  
TDES0[13]: Frame flush  
TDES0[11]: Loss of carrier  
TDES0[10]: No carrier  
TDES0[9]: Late collision  
TDES0[8]: Excessive collision  
TDES0[2]: Excessive deferral  
TDES0[1]: Underflow error  
TDES0[16]: IP header error  
TDES0[12]: IP payload error

**Bit 14 JT:** Jabber timeout

When set, this bit indicates the MAC transmitter has experienced a jabber timeout. This bit is only set when the MAC configuration register's JD bit is not set.

**Bit 13 FF:** Frame flushed

When set, this bit indicates that the DMA/MTL flushed the frame due to a software Flush command given by the CPU.

**Bit 12 IPE:** IP payload error

When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP or ICMP packet bytes received from the application and issues an error status in case of a mismatch.

Bit 11 **LCA**: Loss of carrier

When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the MII\_CRS signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision when the MAC operates in Half-duplex mode.

Bit 10 **NC**: No carrier

When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission.

Bit 9 **LCO**: Late collision

When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times, including preamble, in MII mode). This bit is not valid if the Underflow Error bit is set.

Bit 8 **EC**: Excessive collision

When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the RD (Disable retry) bit in the MAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted.

Bit 7 **VF**: VLAN frame

When set, this bit indicates that the transmitted frame was a VLAN-type frame.

Bits 6:3 **CC**: Collision count

This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive collisions bit (TDES0[8]) is set.

Bit 2 **ED**: Excessive deferral

When set, this bit indicates that the transmission has ended because of excessive deferral of over 24 288 bit times if the Deferral check (DC) bit in the MAC Control register is set high.

Bit 1 **UF**: Underflow error

When set, this bit indicates that the MAC aborted the frame because data arrived late from the RAM memory. Underflow error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit underflow (ETH\_DMASR[5]) and Transmit interrupt (ETH\_DMASR[0]).

Bit 0 **DB**: Deferred bit

When set, this bit indicates that the MAC defers before transmission because of the presence of the carrier. This bit is valid only in Half-duplex mode.

- TDES1: Transmit descriptor Word1**

|          |    |    |      |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |      |    |    |    |    |    |    |    |    |    |    |    |    |

|          |    |    | rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |          |    |    | rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

31:29 Reserved, must be kept at reset value.

28:16 **TBS2**: Transmit buffer 2 size

These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set.

15:13 Reserved, must be kept at reset value.

12:0 **TBS1**: Transmit buffer 1 size

These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]).

- **TDES2: Transmit descriptor Word2**

TDES2 contains the address pointer to the first buffer of the descriptor or it contains time stamp data.

|                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| TBAP1/TBAP/TTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| rw              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 **TBAP1**: Transmit buffer 1 address pointer / Transmit frame time stamp low

These bits have two different functions: they indicate to the DMA the location of data in memory, and after all data are transferred, the DMA can then use these bits to pass back time stamp data.

**TBAP**: When the software makes this descriptor available to the DMA (at the moment that the OWN bit is set to 1 in TDES0), these bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See [Host data buffer alignment](#) for further details on buffer address alignment.

**TTSL**: Before it clears the OWN bit in TDES0, the DMA updates this field with the 32 least significant bits of the time stamp captured for the corresponding transmit frame (overwriting the value for TBAP1). This field has the time stamp only if time stamping is activated for this frame (see TTSE, TDES0 bit 25) and if the Last segment control bit (LS) in the descriptor is set.

- **TDES3: Transmit descriptor Word3**

TDES3 contains the address pointer either to the second buffer of the descriptor or the next descriptor, or it contains time stamp data.

|                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TBAP2/TBAP2/TTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| rw               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 **TBAP2**: Transmit buffer 2 address pointer (Next descriptor address) / Transmit frame time stamp high

These bits have two different functions: they indicate to the DMA the location of data in memory, and after all data are transferred, the DMA can then use these bits to pass back time stamp data.

**TBAP2**: When the software makes this descriptor available to the DMA (at the moment when the OWN bit is set to 1 in TDES0), these bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second address chained (TDES1 [20]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1 [20] is set. (LSBs are ignored internally.)

**TTSH**: Before it clears the OWN bit in TDES0, the DMA updates this field with the 32 most significant bits of the time stamp captured for the corresponding transmit frame (overwriting the value for TBAP2). This field has the time stamp only if time stamping is activated for this frame (see TDES0 bit 25, TTSE) and if the Last segment control bit (LS) in the descriptor is set.

### Enhanced Tx DMA descriptors

Enhanced descriptors (enabled with EDFE=1, ETHDMABMR bit 7), must be used if time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10).

Enhanced descriptors comprise eight 32-bit words, twice the size of normal descriptors. TDES0, TDES1, TDES2 and TDES3 have the same definitions as for normal transmit descriptors (refer to [Normal Tx DMA descriptors](#)). TDES6 and TDES7 hold the time stamp. TDES4, TDES5, TDES6 and TDES7 are defined below.

When the Enhanced descriptor mode is selected, the software needs to allocate 32-bytes (8 words) of memory for every descriptor. When time stamping or IPv4 checksum offload are not being used, the enhanced descriptor format may be disabled and the software can use normal descriptors with the default size of 16 bytes.

|        |                                                           |                 |                                |            |                 |                     |                     |               |                               |  |   |  |  |  |  |  |  |  |  |  |

| rw   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 **TTSH**: Transmit frame time stamp high

This field is updated by DMA with the 32 most significant bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last segment control bit (LS) in the descriptor is set.

### 33.6.8 Rx DMA configuration

The Receive DMA engine's reception sequence is illustrated in [Figure 381](#) and described below:

1. The CPU sets up Receive descriptors (RDES0-RDES3) and sets the OWN bit (RDES0[31]).
2. Once the SR (ETH\_DMAOMR register[1]) bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the CPU), the DMA enters the Suspend state and jumps to Step 9.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to step 7. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor error bit in RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the OWN bit) and marks it as intermediate by clearing the Last segment (LS) bit in the RDES1 value (marks it as last descriptor if flushing is not disabled), then proceeds to step 8. If the DMA owns the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and returns to step 4.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the received frame's status and writes the status word to the current descriptor's RDES0, with the OWN bit cleared and the Last segment bit set.
8. The Receive engine checks the latest descriptor's OWN bit. If the CPU owns the descriptor (OWN bit is at 0) the Receive buffer unavailable bit (in ETH\_DMASR register[7]) is set and the DMA Receive engine enters the Suspended state (step 9). If the DMA owns the descriptor, the engine returns to step 4 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the Receive FIFO (you can control flushing using bit 24 in the ETH\_DMAOMR register).
10. The Receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the Receive FIFO. The engine proceeds to step 2 and re-fetches the next descriptor.

### Receive descriptor acquisition

The receive engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is/are satisfied:

- The receive Start/Stop bit (ETH\_DMAOMR register[1]) has been set immediately after the DMA has been placed in the Run state.
- The data buffer of the current descriptor is full before the end of the frame currently being transferred
- The controller has completed frame reception, but the current receive descriptor has not yet been closed.
- The receive process has been suspended because of a CPU-owned buffer (RDES0[31] = 0) and a new frame is received.
- A Receive poll demand has been issued.

### Receive frame processing

The MAC transfers the received frames to the STM32F4xx memory only when the frame passes the address filter and the frame size is greater than or equal to the configurable threshold bytes set for the Receive FIFO, or when the complete frame is written to the FIFO in Store-and-forward mode. If the frame fails the address filtering, it is dropped in the MAC block itself (unless Receive All ETH\_MACFFR [31] bit is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the Receive FIFO. After 64 (configurable threshold) bytes have been received, the DMA block begins transferring the frame data to the receive buffer pointed to by the current descriptor. The DMA sets the first descriptor (RDES0[9]) after the DMA AHB Interface becomes ready to receive a data transfer (if DMA is not fetching transmit data from the memory), to delimit the frame. The descriptors are released when the OWN (RDES0[31]) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both the last descriptor (RDES0[8]) and first descriptor (RDES0[9]) bits are set. The DMA fetches the next descriptor, sets the last descriptor (RDES0[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets the receive interrupt bit (ETH\_DMASR register [6]). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the CPU. If this occurs, the receive process sets the receive buffer unavailable bit (ETH\_DMASR register[7]) and then enters the Suspend state. The position in the receive list is retained.

### Receive process suspended

If a new receive frame arrives while the receive process is in Suspend state, the DMA re-fetches the current descriptor in the STM32F4xx memory. If the descriptor is now owned by the DMA, the receive process re-enters the Run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the Rx FIFO and increments the missed frame counter. If more than one frame is stored in the Rx FIFO, the process repeats. The discarding or flushing of the frame at the top of the Rx FIFO can be avoided by setting the DMA Operation mode register bit 24 (DFRF). In such conditions, the receive process sets the receive buffer unavailable status bit and returns to the Suspend state.

### Normal Rx DMA descriptors

The normal receive descriptor structure consists of four 32-bit words (16 bytes). These are shown in [Figure 382](#). The bit descriptions of RDES0, RDES1, RDES2 and RDES3 are given below.

Note that enhanced descriptors must be used if time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10).

**Figure 382. Normal Rx DMA descriptor structure**

- #### RDES0: Receive descriptor Word0

RDES0 contains the received frame status, the frame length and the descriptor ownership information.

**Bit 31 OWN:** Own bit

When set, this bit indicates that the descriptor is owned by the DMA of the MAC Subsystem. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.

**Bit 30 AFM:** Destination address filter fail

When set, this bit indicates a frame that failed the DA filter in the MAC Core.

**Bits 29:16 FL:** Frame length

These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid only when last descriptor (RDES0[8]) is set and descriptor error (RDES0[14]) is reset.

This field is valid when last descriptor (RDES0[8]) is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.

- Bit 15 **ES**: Error summary  
 Indicates the logical OR of the following bits:  
 RDES0[1]: CRC error  
 RDES0[3]: Receive error  
 RDES0[4]: Watchdog timeout  
 RDES0[6]: Late collision  
 RDES0[7]: Giant frame (This is not applicable when RDES0[7] indicates an IPV4 header checksum error.)  
 RDES0[11]: Overflow error  
 RDES0[14]: Descriptor error.  
 This field is valid only when the last descriptor (RDES0[8]) is set.
- Bit 14 **DE**: Descriptor error  
 When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the next descriptor. The frame is truncated.  
 This field is valid only when the last descriptor (RDES0[8]) is set.
- Bit 13 **SAF**: Source address filter fail  
 When set, this bit indicates that the SA field of frame failed the SA filter in the MAC Core.
- Bit 12 **LE**: Length error  
 When set, this bit indicates that the actual length of the received frame does not match the value in the Length/ Type field. This bit is valid only when the Frame type (RDES0[5]) bit is reset.
- Bit 11 **OE**: Overflow error  
 When set, this bit indicates that the received frame was damaged due to buffer overflow.
- Bit 10 **VLAN**: VLAN tag  
 When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the MAC core.
- Bit 9 **FS**: First descriptor  
 When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame.
- Bit 8 **LS**: Last descriptor  
 When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame.
- Bit 7 **IPHCE/TSV**: IPv header checksum error / time stamp valid  
 If IPHCE is set, it indicates an error in the IPv4 or IPv6 header. This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. This bit can take on special meaning as specified in [Table 194](#).  
 If enhanced descriptor format is enabled (EDFE=1, bit 7 of ETH\_DMABMR), this bit takes on the TSV function (otherwise it is IPHCE). When TSV is set, it indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). TSV is valid only when the Last descriptor bit (RDES0[8]) is set.
- Bit 6 **LCO**: Late collision  
 When set, this bit indicates that a late collision has occurred while receiving the frame in Half-duplex mode.

**Bit 5 FT:** Frame type

When set, this bit indicates that the Receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. When the normal descriptor format is used (ETH\_DMABMR EDFE=0), FT can take on special meaning as specified in [Table 194](#).

**Bit 4 RWT:** Receive watchdog timeout

When set, this bit indicates that the Receive watchdog timer has expired while receiving the current frame and the current frame is truncated after the watchdog timeout.

**Bit 3 RE:** Receive error

When set, this bit indicates that the RX\_ERR signal is asserted while RX\_DV is asserted during frame reception.

**Bit 2 DE:** Dribble bit error

When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII mode.

**Bit 1 CE:** CRC error

When set, this bit indicates that a cyclic redundancy check (CRC) error occurred on the received frame. This field is valid only when the last descriptor (RDES0[8]) is set.

**Bit 0 PCE/ESA:** Payload checksum error / extended status available

When set, it indicates that the TCP, UDP or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP or ICMP segment's Checksum field. This bit is also set when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame. This bit can take on special meaning as specified in [Table 194](#).

If the enhanced descriptor format is enabled (EDFE=1, bit 7 in ETH\_DMABMR), this bit takes on the ESA function (otherwise it is PCE). When ESA is set, it indicates that the extended status is available in descriptor word 4 (RDES4). ESA is valid only when the last descriptor bit (RDES0[8]) is set.

Bits 5, 7, and 0 reflect the conditions discussed in [Table 194](#).

**Table 194. Receive descriptor 0 - encoding for bits 7, 5 and 0 (normal descriptor format only, EDFE=0)**

| Bit 5: frame type | Bit 7: IPC checksum error | Bit 0: payload checksum error | Frame status                                                                                                        |
|-------------------|---------------------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------|
| 0                 | 0                         | 0                             | IEEE 802.3 Type frame (Length field value is less than 0x0600.)                                                     |
| 1                 | 0                         | 0                             | IPv4/IPv6 Type frame, no checksum error detected                                                                    |
| 1                 | 0                         | 1                             | IPv4/IPv6 Type frame with a payload checksum error (as described for PCE) detected                                  |
| 1                 | 1                         | 0                             | IPv4/IPv6 Type frame with an IP header checksum error (as described for IPC CE) detected                            |
| 1                 | 1                         | 1                             | IPv4/IPv6 Type frame with both IP header and payload checksum errors detected                                       |
| 0                 | 0                         | 1                             | IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload |
| 0                 | 1                         | 1                             | A Type frame that is neither IPv4 or IPv6 (the checksum offload engine bypasses checksum completely.)               |
| 0                 | 1                         | 0                             | Reserved                                                                                                            |

• **RDES1: Receive descriptor Word1**

|     |      |    |      |    |    |    |    |    |    |    |    |    |    |    |    |    |     |    |     |          |     |    |    |    |    |    |    |    |    |    |    |    |  |  |
|-----|------|----|------|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|----|-----|----------|-----|----|----|----|----|----|----|----|----|----|----|----|--|--|
| 31  | 30   | 29 | 28   | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14  | 13 | 12  | 11       | 10  | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |    |  |  |
| DIC | RBS2 |    | RBS2 |    |    |    |    |    |    |    |    |    |    |    |    |    | RER |    | RCH | Reserved | RBS |    |    |    |    |    |    |    |    |    |    |    |  |  |
| rw  | rw   | rw | rw   | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw  | rw | rw  |          | rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |  |  |

Bit 31 **DIC**: Disable interrupt on completion

When set, this bit prevents setting the Status register's RS bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Host due to RS for that frame.

Bits 30:29 Reserved, must be kept at reset value.

Bits 28:16 **RBS2**: Receive buffer 2 size

These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, 8, or 16, depending on the bus widths (32, 64 or 128, respectively), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8 or 16, the resulting behavior is undefined. This field is not valid if RDES1 [14] is set.

Bit 15 **RER**: Receive end of ring

When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.

Bit 14 **RCH**: Second address chained

When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a “don’t care” value. RDES1[15] takes precedence over RDES1[14].

Bit 13 Reserved, must be kept at reset value.

Bits 12:0 **RBS1**: Receive buffer 1 size

Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, 8 or 16, depending upon the bus widths (32, 64 or 128), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, 8 or 16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (bit 14).

- **RDES2: Receive descriptor Word2**

RDES2 contains the address pointer to the first data buffer in the descriptor, or it contains time stamp data.

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RBP1 / RTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw          | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **RBAP1 / RTSL**: Receive buffer 1 address pointer / Receive frame time stamp low

These bits take on two different functions: the application uses them to indicate to the DMA where to store the data in memory, and then after transferring all the data the DMA may use these bits to pass back time stamp data.

**RBAP1**: When the software makes this descriptor available to the DMA (at the moment that the OWN bit is set to 1 in RDES0), these bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: the DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

**RTSL**: Before it clears the OWN bit in RDES0, the DMA updates this field with the 32 least significant bits of the time stamp captured for the corresponding receive frame (overwriting the value for RBAP1). This field has the time stamp only if time stamping is activated for this frame and if the Last segment control bit (LS) in the descriptor is set.

- **RDES3: Receive descriptor Word3**

RDES3 contains the address pointer either to the second data buffer in the descriptor or to the next descriptor, or it contains time stamp data.

Bits 31:0 **RBAP2 / RTSH**: Receive buffer 2 address pointer (next descriptor address) / Receive frame time stamp high

These bits take on two different functions: the application uses them to indicate to the DMA the location of where to store the data in memory, and then after transferring all the data the DMA may use these bits to pass back time stamp data.

**RBAP1**: When the software makes this descriptor available to the DMA (at the moment that the OWN bit is set to 1 in RDES0), these bits indicate the physical address of buffer 2 when a descriptor ring structure is used. If the second address chained (RDES1 [24]) bit is set, this address contains the pointer to the physical memory where the next descriptor is present. If RDES1 [24] is set, the buffer (next descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64 or 32. LSBs are ignored internally.)

However, when RDES1 [24] is reset, there are no limitations on the RDES3 value, except for the following condition: the DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64 or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.

**RTSH**: Before it clears the OWN bit in RDES0, the DMA updates this field with the 32 most significant bits of the time stamp captured for the corresponding receive frame (overwriting the value for RBAP2). This field has the time stamp only if time stamping is activated and if the Last segment control bit (LS) in the descriptor is set.

### Enhanced Rx DMA descriptors format with IEEE1588 time stamp

Enhanced descriptors (enabled with EDFE=1, ETHDMABMR bit 7), must be used if time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10).

Enhanced descriptors comprise eight 32-bit words, twice the size of normal descriptors. RDES0, RDES1, RDES2 and RDES3 have the same definitions as for normal receive descriptors (refer to [Normal Rx DMA descriptors](#)). RDES4 contains extended status while RDES6 and RDES7 hold the time stamp. RDES4, RDES5, RDES6 and RDES7 are defined below.

When the Enhanced descriptor mode is selected, the software needs to allocate 32 bytes (8 words) of memory for every descriptor. When time stamping or IPv4 checksum offload are not being used, the enhanced descriptor format may be disabled and the software can use normal descriptors with the default size of 16 bytes.

Figure 383. Enhanced receive descriptor field format with IEEE1588 time stamp enabled

• RDES4: Receive descriptor Word4

The extended status, shown below, is valid only when there is status related to IPv4 checksum or time stamp available as indicated by bit 0 in RDES0.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **PV**: PTP version

When set, indicates that the received PTP message uses the IEEE 1588 version 2 format. When cleared, it uses version 1 format. This is valid only if the message type is non-zero.

Bit 12 **PFT**: PTP frame type

When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is cleared and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7.

Bits 11:8 **PMT**: PTP message type

These bits are encoded to give the type of the message received.

- 0000: No PTP message received
- 0001: SYNC (all clock types)
- 0010: Follow\_Up (all clock types)
- 0011: Delay\_Req (all clock types)
- 0100: Delay\_Resp (all clock types)
- 0101: Pdelay\_Req (in peer-to-peer transparent clock) or Announce (in ordinary or boundary clock)
- 0110: Pdelay\_Resp (in peer-to-peer transparent clock) or Management (in ordinary or boundary clock)
- 0111: Pdelay\_Resp\_Follow\_Up (in peer-to-peer transparent clock) or Signaling (for ordinary or boundary clock)
- 1xxx - Reserved

Bit 7 **IPV6PR**: IPv6 packet received

When set, this bit indicates that the received packet is an IPv6 packet.

Bit 6 **IPV4PR**: IPv4 packet received

When set, this bit indicates that the received packet is an IPv4 packet.

Bit 5 **IPCB**: IP checksum bypassed

When set, this bit indicates that the checksum offload engine is bypassed.

Bit 4 **IPPE**: IP payload error

When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field.

Bit 3 **IPHE**: IP header error

When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value.

Bits 2:0 **IPPT**: IP payload type

if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCR bit 10), these bits indicate the type of payload encapsulated in the IP datagram. These bits are '00' if there is an IP header error or fragmented IP.

- 000: Unknown or did not process IP payload
- 001: UDP
- 010: TCP
- 011: ICMP
- 1xx: Reserved

- **RDES5**: Receive descriptor Word5

Reserved.

- **RDES6**: Receive descriptor Word6

The table below describes the fields that have different meaning for RDES6 when the receive descriptor is closed and time stamping is enabled.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RTSL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **RTSL**: Receive frame time stamp low

The DMA updates this field with the 32 least significant bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by last descriptor status bit (RDES0[8]). When this field and the RTSH field in RDES7 show all ones, the time stamp must be treated as corrupt.

- **RDES7: Receive descriptor Word7**

The table below describes the fields that have a different meaning for RDES7 when the receive descriptor is closed and time stamping is enabled.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| RTSH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **RTSH**: Receive frame time stamp high

The DMA updates this field with the 32 most significant bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by last descriptor status bit (RDES0[8]).

When this field and RDES7's RTSL field show all ones, the time stamp must be treated as corrupt.

### 33.6.9 DMA interrupts

Interrupts can be generated as a result of various events. The ETH\_DMASR register contains all the bits that might cause an interrupt. The ETH\_DMAIER register contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, Normal and Abnormal, as described in the ETH\_DMASR register. Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. If the MAC core is the cause for assertion of the interrupt, then any of the TSTS or PMTS bits in the ETH\_DMASR register is set high.

Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, the Receive Interrupt bit (ETH\_DMASR register [6]) indicates that one or more frames were transferred to the STM32F4xx buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the ETH\_DMASR register for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in the ETH\_DMASR register. For example, the controller generates a Receive interrupt (ETH\_DMASR register[6]) and the driver begins reading the ETH\_DMASR register. Next, receive buffer unavailable (ETH\_DMASR register[7]) occurs. The driver clears the Receive interrupt. Even then, a new interrupt is generated, due to the active or pending Receive buffer unavailable interrupt.

Figure 384. Interrupt scheme

AI15646

### 33.7 Ethernet interrupts

The Ethernet controller has two interrupt vectors: one dedicated to normal Ethernet operations and the other, used only for the Ethernet wake-up event (with wake-up frame or Magic Packet detection) when it is mapped on EXTI line 19.

The first Ethernet vector is reserved for interrupts generated by the MAC and the DMA as listed in the [MAC interrupts](#) and [DMA interrupts](#) sections.

The second vector is reserved for interrupts generated by the PMT on wake-up events. The mapping of a wake-up event on EXTI line 19 causes the STM32F4xx to exit the low-power mode, and generates an interrupt.

When an Ethernet wake-up event mapped on EXTI Line 19 occurs and the MAC PMT interrupt is enabled and the EXTI Line 19 interrupt, with detection on rising edge, is also enabled, both interrupts are generated.

A watchdog timer (see ETH\_DMARSWTR register) is given for flexible control of the RS bit (ETH\_DMA\_SR register). When this watchdog timer is programmed with a non-zero value, it gets activated as soon as the RxDMA completes a transfer of a received frame to system memory without asserting the Receive Status because it is not enabled in the corresponding Receive descriptor (RDES1[31]). When this timer runs out as per the programmed value, the RS bit is set and the interrupt is asserted if the corresponding RIE is enabled in the ETH\_DMAIER register. This timer is disabled before it runs out, when a frame is transferred to memory and the RS is set because it is enabled for that descriptor.

**Note:** Reading the PMT control and status register automatically clears the Wake-up Frame Received and Magic Packet Received PMT interrupt flags. However, since the registers for these flags are in the CLK\_RX domain, there may be a significant delay before this update is visible by the firmware. The delay is especially long when the RX clock is slow (in 10 Mbit mode) and when the AHB bus is high-frequency.

Since interrupt requests from the PMT to the CPU are based on the same registers in the CLK\_RX domain, the CPU may spuriously call the interrupt routine a second time even after reading PMT\_CSR. Thus, it may be necessary that the firmware polls the Wake-up Frame Received and Magic Packet Received bits and exits the interrupt service routine only when they are found to be at '0'.

## 33.8 Ethernet register descriptions

The peripheral registers can be accessed by bytes (8-bit), half-words (16-bit) or words (32-bits).

### 33.8.1 MAC register description

#### Ethernet MAC configuration register (ETH\_MACCR)

Address offset: 0x0000

Reset value: 0x0000 8000

The MAC configuration register is the operation mode register of the MAC. It establishes receive and transmit operating modes.

| 31       | 30 | 29 | 28 | 27 | 26 | 25   | 24       | 23 | 22 | 21       | 20  | 19  | 18       | 17  | 16  | 15 | 14 | 13  | 12 | 11       | 10   | 9  | 8  | 7  | 6  | 5        | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|------|----------|----|----|----------|-----|-----|----------|-----|-----|----|----|-----|----|----------|------|----|----|----|----|----------|---|---|---|---|---|
| Reserved |    |    |    |    |    | CSTF | Reserved | WD | JD | Reserved | IFG | CSD | Reserved | FES | ROD | LM | DM | PCO | RD | Reserved | APCS | BL | DC | TE | RE | Reserved |   |   |   |   |   |
|          |    |    |    |    |    | rw   |          | rw | rw |          | rw  | rw  |          | rw  | rw  | rw | rw | rw  | rw |          | rw   | rw | rw | rw | rw |          |   |   |   |   |   |

Bits 31:26 Reserved, must be kept at reset value.

**CSTF:** CRC stripping for Type frames

Bit 25 When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **WD:** Watchdog disable

When this bit is set, the MAC disables the watchdog timer on the receiver, and can receive frames of up to 16 384 bytes.

When this bit is reset, the MAC allows no more than 2 048 bytes of the frame being received and cuts off any bytes received after that.

Bit 22 **JD:** Jabber disable

When this bit is set, the MAC disables the jabber timer on the transmitter, and can transfer frames of up to 16 384 bytes.

When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2 048 bytes of data during transmission.

Bits 21:20 Reserved, must be kept at reset value.

Bits 19:17 **IFG**: Interframe gap

These bits control the minimum interframe gap between frames during transmission.

000: 96 bit times

001: 88 bit times

010: 80 bit times

....

111: 40 bit times

*Note: In Half-duplex mode, the minimum IFG can be configured for 64 bit times (IFG = 100) only. Lower values are not considered.*

Bit 16 **CSD**: Carrier sense disable

When set high, this bit makes the MAC transmitter ignore the MII CRS signal during frame transmission in Half-duplex mode. No error is generated due to Loss of Carrier or No Carrier during such transmission.

When this bit is low, the MAC transmitter generates such errors due to Carrier Sense and even aborts the transmissions.

## Bit 15 Reserved, must be kept at reset value.

Bit 14 **FES**: Fast Ethernet speed

Indicates the speed in Fast Ethernet (MII) mode:

0: 10 Mbit/s

1: 100 Mbit/s

Bit 13 **ROD**: Receive own disable

When this bit is set, the MAC disables the reception of frames in Half-duplex mode.

When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting.

This bit is not applicable if the MAC is operating in Full-duplex mode.

Bit 12 **LM**: Loopback mode

When this bit is set, the MAC operates in loopback mode at the MII. The MII receive clock input (RX\_CLK) is required for the loopback to work properly, as the transmit clock is not looped-back internally.

Bit 11 **DM**: Duplex mode

When this bit is set, the MAC operates in a Full-duplex mode where it can transmit and receive simultaneously.

Bit 10 **IPCO**: IPv4 checksum offload

When set, this bit enables IPv4 checksum checking for received frame payloads' TCP/UDP/ICMP headers. When this bit is reset, the checksum offload function in the receiver is disabled and the corresponding PCE and IP HCE status bits (see [Table 191](#)) are always cleared.

Bit 9 **RD**: Retry disable

When this bit is set, the MAC attempts only 1 transmission. When a collision occurs on the MII, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status.

When this bit is reset, the MAC attempts retries based on the settings of BL.

*Note: This bit is applicable only in the Half-duplex mode.*

## Bit 8 Reserved, must be kept at reset value.

**Bit 7 APCS:** Automatic pad/CRC stripping

When this bit is set, the MAC strips the Pad/FCS field on incoming frames only if the length's field value is less than or equal to 1 500 bytes. All received frames with length field greater than or equal to 1 501 bytes are passed on to the application without stripping the Pad/FCS field.

When this bit is reset, the MAC passes all incoming frames unmodified.

**Bits 6:5 BL:** Back-off limit

The Back-off limit determines the random integer number ( $r$ ) of slot time delays (4 096 bit times for 1000 Mbit/s and 512 bit times for 10/100 Mbit/s) the MAC waits before rescheduling a transmission attempt during retries after a collision.

*Note: This bit is applicable only to Half-duplex mode.*

00:  $k = \min(n, 10)$

01:  $k = \min(n, 8)$

10:  $k = \min(n, 4)$

11:  $k = \min(n, 1)$ ,

where  $n = \text{retransmission attempt}$ . The random integer  $r$  takes the value in the range  $0 \leq r < 2^k$

**Bit 4 DC:** Deferral check

When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status when the transmit state machine is deferred for more than 24 288 bit times in 10/100-Mbit/s mode. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active CRS (carrier sense) signal on the MII. Defer time is not cumulative. If the transmitter defers for 10 000 bit times, then transmits, collides, backs off, and then has to defer again after completion of back-off, the deferral timer resets to 0 and restarts.

When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in Half-duplex mode.

**Bit 3 TE:** Transmitter enable

When this bit is set, the transmit state machine of the MAC is enabled for transmission on the MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames.

**Bit 2 RE:** Receiver enable

When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the MII.

**Bits 1:0** Reserved, must be kept at reset value.

**Ethernet MAC frame filter register (ETH\_MACFFR)**

Address offset: 0x0004

Reset value: 0x0000 0000

The MAC frame filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as pass bad frames and pass control frames.

|    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |      |     |    |     |     |      |    |    |    |
|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|------|-----|----|-----|-----|------|----|----|----|
| 31 | 30       | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10  | 9   | 8    | 7   | 6  | 5   | 4   | 3    | 2  | 1  | 0  |
| RA | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | HPF | SAF | SAIF | PCF |    | BFD | PAM | DAIF | HM | HU | PM |
| rw |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw  | rw  | rw   | rw  | rw | rw  | rw  | rw   | rw | rw | rw |

**Bit 31 RA:** Receive all

When this bit is set, the MAC receiver passes all received frames on to the application, irrespective of whether they have passed the address filter. The result of the SA/DA filtering is updated (pass or fail) in the corresponding bits in the receive status word. When this bit is reset, the MAC receiver passes on to the application only those frames that have passed the SA/DA address filter.

Bits 30:11 Reserved, must be kept at reset value.

**Bit 10 HPF:** Hash or perfect filter

When this bit is set and if the HM or HU bit is set, the address filter passes frames that match either the perfect filtering or the hash filtering.

When this bit is cleared and if the HU or HM bit is set, only frames that match the Hash filter are passed.

**Bit 9 SAF:** Source address filter

The MAC core compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SAMatch bit in the RxStatus word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC core forwards the received frame to the application. It also forwards the updated SA Match bit in RxStatus depending on the SA address comparison.

**Bit 8 SAIF:** Source address inverse filtering

When this bit is set, the address check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA address filter.

When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA address filter.

**Bits 7:6 PCF:** Pass control frames

These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). Note that the processing of PAUSE control frames depends only on RFCE in Flow Control Register[2].

00: MAC prevents all control frames from reaching the application

01: MAC forwards all control frames to application except Pause control frames

10: MAC forwards all control frames to application even if they fail the address filter

11: MAC forwards control frames that pass the address filter.

These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). Note that the processing of PAUSE control frames depends only on RFCE in Flow Control register[2].

00 or 01: MAC prevents all control frames from reaching the application

10: MAC forwards all control frames to application even if they fail the address filter

11: MAC forwards control frames that pass the address filter.

**Bit 5 BFD:** Broadcast frames disable

When this bit is set, the address filters filter all incoming broadcast frames.

When this bit is reset, the address filters pass all received broadcast frames.

**Bit 4 PAM:** Pass all multicast

When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed.

When reset, filtering of multicast frame depends on the HM bit.

**Bit 3 DAIF:** Destination address inverse filtering

When this bit is set, the address check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames.

When reset, normal filtering of frames is performed.

**Bit 2 HM:** Hash multicast

When set, MAC performs destination address filtering of received multicast frames according to the hash table.

When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers.

**Bit 1 HU:** Hash unicast

When set, MAC performs destination address filtering of unicast frames according to the hash table.

When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers.

**Bit 0 PM:** Promiscuous mode

When this bit is set, the address filters pass all incoming frames regardless of their destination or source address. The SA/DA filter fails status bits in the receive status word are always cleared when PM is set.

**Ethernet MAC hash table high register (ETH\_MACHTHR)**

Address offset: 0x0008

Reset value: 0x0000 0000

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame are passed through the CRC logic, and the upper 6 bits in the CRC register are used to index the contents of the Hash table. This CRC is a 32-bit value coded by the following polynomial (for more details refer to [Section 33.5.3](#)):

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The most significant bit determines the register to be used (hash table high/hash table low), and the other 5 bits determine which bit within the register. A hash value of 0b0 0000 selects bit 0 in the selected register, and a value of 0b1 1111 selects bit 31 in the selected register.

For example, if the DA of the incoming frame is received as 0x1F52 419C B6AF (0x1F is the first byte received on the MII interface), then the internally calculated 6-bit Hash value is 0x2C and the HTH register bit[12] is checked for filtering. If the DA of the incoming frame is received as 0xA00A 9800 0045, then the calculated 6-bit Hash value is 0x07 and the HTL register bit[7] is checked for filtering.

If the corresponding bit value in the register is 1, the frame is accepted. Otherwise, it is rejected. If the PAM (pass all multicast) bit is set in the ETH\_MACFFR register, then all multicast frames are accepted regardless of the multicast hash values.

The Hash table high register contains the higher 32 bits of the multicast Hash table.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| HTH |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **HTH**: Hash table high

This field contains the upper 32 bits of Hash table.

### Ethernet MAC hash table low register (ETH\_MACHTLR)

Address offset: 0x000C

Reset value: 0x0000 0000

The Hash table low register contains the lower 32 bits of the multi-cast Hash table.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| HTL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **HTL**: Hash table low

This field contains the lower 32 bits of the Hash table.

### Ethernet MAC MII address register (ETH\_MACMIAR)

Address offset: 0x0010

Reset value: 0x0000 0000

The MII address register controls the management cycles to the external PHY through the management interface.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:11 **PA**: PHY address

This field tells which of the 32 possible PHY devices are being accessed.

Bits 10:6 **MR**: MII register

These bits select the desired MII register in the selected PHY device.

Bit 5 Reserved, must be kept at reset value.

Bits 4:2 **CR**: Clock range

The CR clock range selection determines the HCLK frequency and is used to decide the frequency of the MDC clock:

Selection HCLK MDC clock

000 60-100 MHz HCLK/42

001 100-150 MHz HCLK/62

010 20-35 MHz HCLK/16

011 35-60 MHz HCLK/26

100 150-180 MHz HCLK/102

101, 110, 111 Reserved -

Bit 1 **MW**: MII write

When set, this bit tells the PHY that this is a Write operation using the MII Data register. If this bit is not set, this is a Read operation, placing the data in the MII Data register.

Bit 0 **MB**: MII busy

This bit should read a logic 0 before writing to ETH\_MACMIAR and ETH\_MACMIIDR. This bit must also be reset to 0 during a Write to ETH\_MACMIAR. During a PHY register access, this bit is set to 0b1 by the application to indicate that a read or write access is in progress. ETH\_MACMIIDR (MII Data) should be kept valid until this bit is cleared by the MAC during a PHY Write operation. The ETH\_MACMIIDR is invalid until this bit is cleared by the MAC during a PHY Read operation. The ETH\_MACMIAR (MII Address) should not be written to until this bit is cleared.

### Ethernet MAC MII data register (ETH\_MACMIIDR)

Address offset: 0x0014

Reset value: 0x0000 0000

The MAC MII Data register stores write data to be written to the PHY register located at the address specified in ETH\_MACMIAR. ETH\_MACMIIDR also stores read data from the PHY register located at the address specified by ETH\_MACMIAR.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MD**: MII data

This contains the 16-bit data value read from the PHY after a Management Read operation, or the 16-bit data value to be written to the PHY before a Management Write operation.

**Ethernet MAC flow control register (ETH\_MACFCR)**

Address offset: 0x0018

Reset value: 0x0000 0000

The Flow control register controls the generation and reception of the control (Pause Command) frames by the MAC. A write to a register with the Busy bit set to '1' causes the MAC to generate a pause control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6        | 5   | 4  | 3    | 2    | 1    | 0        |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|------|----------|-----|----|------|------|------|----------|
| PT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Reserved |    |    |    |    |    |   |   | ZQPD | Reserved | PLT |    | UPFD | RFCE | TFCE | FCB/BPA  |
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |          |    |    |    |    |    |   |   | rw   |          | rw  | rw | rw   | rw   | rw   | rc_w1/rw |

**Bits 31:16 PT:** Pause time

This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the MII clock domain, then consecutive write operations to this register should be performed only after at least 4 clock cycles in the destination clock domain.

Bits 15:8 **Reserved**, must be kept at reset value.

**Bit 7 ZQPD:** Zero-quanta pause disable

When set, this bit disables the automatic generation of Zero-quanta pause control frames on the deassertion of the flow-control signal from the FIFO layer.

When this bit is reset, normal operation with automatic Zero-quanta pause control frame generation is enabled.

Bit 6 **Reserved**, must be kept at reset value.

**Bits 5:4 PLT:** Pause low threshold

This field configures the threshold of the Pause timer at which the Pause frame is automatically retransmitted. The threshold values should always be less than the Pause Time configured in bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if initiated at 228 (256 – 28) slot-times after the first PAUSE frame is transmitted.

Selection Threshold

- 00 Pause time minus 4 slot times
- 01 Pause time minus 28 slot times
- 10 Pause time minus 144 slot times
- 11 Pause time minus 256 slot times

Slot time is defined as time taken to transmit 512 bits (64 bytes) on the MII interface.

**Bit 3 UPFD:** Unicast pause frame detect

When this bit is set, the MAC detects the Pause frames with the station's unicast address specified in the ETH\_MACA0HR and ETH\_MACA0LR registers, in addition to detecting Pause frames with the unique multicast address.

When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard.

**Bit 2 RFCE:** Receive flow control enable

When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause Time) time.

When this bit is reset, the decode function of the Pause frame is disabled.

**Bit 1 TFCE:** Transmit flow control enable

In Full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames.

In Half-duplex mode, when this bit is set, the MAC enables the back-pressure operation.

When this bit is reset, the back pressure feature is disabled.

**Bit 0 FCB/BPA:** Flow control busy/back pressure activate

This bit initiates a Pause Control frame in Full-duplex mode and activates the back pressure function in Half-duplex mode if TFCE bit is set.

In Full-duplex mode, this bit should be read as 0 before writing to the Flow control register.

To initiate a Pause control frame, the Application must set this bit to 1. During a transfer of the Control frame, this bit continues to be set to signify that a frame transmission is in progress. After completion of the Pause control frame transmission, the MAC resets this bit to 0. The Flow control register should not be written to until this bit is cleared.

In Half-duplex mode, when this bit is set (and TFCE is set), back pressure is asserted by the MAC core. During back pressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured to Full-duplex mode, the BPA is automatically disabled.

**Ethernet MAC VLAN tag register (ETH\_MACVLANTR)**

Address offset: 0x001C

Reset value: 0x0000 0000

The VLAN tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13<sup>th</sup> and 14<sup>th</sup> bytes of the receiving frame (Length/Type) with 0x8100, and the following 2 bytes are compared with the VLAN tag; if a match occurs, the received VLAN bit in the receive frame status is set. The legal length of the frame is increased from 1518 bytes to 1522 bytes.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16     | 15     | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    | VLANTC | VLANTI |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        | r/w    | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **VLANTC**: 12-bit VLAN tag comparison

When this bit is set, a 12-bit VLAN identifier, rather than the complete 16-bit VLAN tag, is used for comparison and filtering. Bits[11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged frame.  
When this bit is reset, all 16 bits of the received VLAN frame's fifteenth and sixteenth bytes are used for comparison.

Bits 15:0 **VLANTI**: VLAN tag identifier (for receive frames)

This contains the 802.1Q VLAN tag to identify VLAN frames, and is compared to the fifteenth and sixteenth bytes of the frames being received for VLAN frames. Bits[15:13] are the user priority, Bit[12] is the canonical format indicator (CFI) and bits[11:0] are the VLAN tag's VLAN identifier (VID) field. When the VLANTC bit is set, only the VID (bits[11:0]) is used for comparison.  
If VLANTI (VLANTI[11:0] if VLANTC is set) is all zeros, the MAC does not check the fifteenth and sixteenth bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 as VLAN frames.

### Ethernet MAC remote wake-up frame filter register (ETH\_MACRWUFR)

Address offset: 0x0028

Reset value: 0x0000 0000

This is the address through which the remote wake-up frame filter registers are written/read by the application. The Wake-up frame filter register is actually a pointer to eight (not transparent) such wake-up frame filter registers. Eight sequential write operations to this address with the offset (0x0028) write all wake-up frame filter registers. Eight sequential read operations from this address with the offset (0x0028) read all wake-up frame filter registers. This register contains the higher 16 bits of the 7<sup>th</sup> MAC address. Refer to [Remote wake-up frame filter register](#) section for additional information.

**Figure 385. Ethernet MAC remote wake-up frame filter register (ETH\_MACRWUFR)**

|                          |                    |                  |                 |                  |                   |                  |                 |                  |

ai15648

ai15648

**Ethernet MAC PMT control and status register (ETH\_MACPMTCSR)**

Address offset: 0x002C

Reset value: 0x0000 0000

The ETH\_MACPMTCSR programs the request wake-up events and monitors the wake-up events.

|        |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |   |      |      |          |   |     |     |    |

Bit 31 **WFFRPR**: Wake-up frame filter register pointer reset

When set, it resets the Remote wake-up frame filter register pointer to 0b000. It is automatically cleared after 1 clock cycle.

Bits 30:10 Reserved, must be kept at reset value.

Bit 9 **GU**: Global unicast

When set, it enables any unicast packet filtered by the MAC (DAF) address recognition to be a wake-up frame.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **WFR**: Wake-up frame received

When set, this bit indicates the power management event was generated due to reception of a wake-up frame. This bit is cleared by a read into this register.

Bit 5 **MPR**: Magic packet received

When set, this bit indicates the power management event was generated by the reception of a Magic Packet. This bit is cleared by a read into this register.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **WFE**: Wake-up frame enable

When set, this bit enables the generation of a power management event due to wake-up frame reception.

Bit 1 **MPE**: Magic Packet enable

When set, this bit enables the generation of a power management event due to Magic Packet reception.

Bit 0 **PD**: Power down

When this bit is set, all received frames are dropped. This bit is cleared automatically when a magic packet or wake-up frame is received, and Power-down mode is disabled. Frames received after this bit is cleared are forwarded to the application. This bit must only be set when either the Magic Packet Enable or Wake-up Frame Enable bit is set high.

**Ethernet MAC debug register (ETH\_MACDBG)**

Address offset: 0x0034

Reset value: 0x0000 0000

This debug register gives the status of all the main modules of the transmit and receive data paths and the FIFOs. An all-zero status indicates that the MAC core is in Idle state (and FIFOs are empty) and no activity is going on in the data paths.

| 31       | 30 | 29 | 28 | 27 | 26 | 25  | 24   | 23       | 22   | 21   | 20 | 19 | 18  | 17    | 16 | 15    | 14       | 13 | 12 | 11 | 10 | 9 | 8    | 7  | 6        | 5     | 4  | 3     | 2        | 1       | 0  |        |

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **TFF**: Tx FIFO full

When high, it indicates that the Tx FIFO is full and hence no more frames are accepted for transmission.

Bit 24 **TFNE**: Tx FIFO not empty

When high, it indicates that the Tx FIFO is not empty and has some data left for transmission.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **TFWA**: Tx FIFO write active

When high, it indicates that the Tx FIFO write controller is active and transferring data to the Tx FIFO.

Bits 21:20 **TFRS**: Tx FIFO read status

This indicates the state of the Tx FIFO read controller:

00: Idle state

01: Read state (transferring data to the MAC transmitter)

10: Waiting for TxStatus from MAC transmitter

11: Writing the received TxStatus or flushing the Tx FIFO

Bit 19 **MTP**: MAC transmitter in pause

When high, it indicates that the MAC transmitter is in Pause condition (in full-duplex mode only) and hence does not schedule any frame for transmission

Bits 18:17 **MTFCS**: MAC transmit frame controller status

This indicates the state of the MAC transmit frame controller:

00: Idle

01: Waiting for Status of previous frame or IFG/backoff period to be over

10: Generating and transmitting a Pause control frame (in full duplex mode)

11: Transferring input frame for transmission

Bit 16 **MMTEA**: MAC MII transmit engine active

When high, it indicates that the MAC MII transmit engine is actively transmitting data and that it is not in the Idle state.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **RFLL**: Rx FIFO fill level

This gives the status of the Rx FIFO fill-level:

- 00: RxFIFO empty
- 01: RxFIFO fill-level below flow-control de-activate threshold
- 10: RxFIFO fill-level above flow-control activate threshold
- 11: RxFIFO full

Bit 7 Reserved, must be kept at reset value.

Bits 6:5 **RFRCS**: Rx FIFO read controller status

It gives the state of the Rx FIFO read controller:

- 00: IDLE state
- 01: Reading frame data
- 10: Reading frame status (or time-stamp)
- 11: Flushing the frame data and status

Bit 4 **RFWRA**: Rx FIFO write controller active

When high, it indicates that the Rx FIFO write controller is active and transferring a received frame to the FIFO.

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **MSFRWCS**: MAC small FIFO read / write controllers status

When high, these bits indicate the respective active state of the small FIFO read and write controllers of the MAC receive frame controller module.

Bit 0 **MMRPEA**: MAC MII receive protocol engine active

When high, it indicates that the MAC MII receive protocol engine is actively receiving data and is not in the Idle state.

**Ethernet MAC interrupt status register (ETH\_MACSR)**

Address offset: 0x0038

Reset value: 0x0000 0000

The ETH\_MACSR register contents identify the events in the MAC that can generate an interrupt.

|          |    |    |    |    |    | rc_r |          |   | r     | r     | r    | r    |          |   |   |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **TSTS**: Time stamp trigger status

This bit is set high when the system time value equals or exceeds the value specified in the Target time high and low registers. This bit is cleared by reading the ETH\_PTPTSSR register.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **MMCTS**: MMC transmit status

This bit is set high whenever an interrupt is generated in the [Ethernet MMC transmit interrupt register \(ETH\\_MMCTIR\)](#). This bit is cleared when all the bits in this interrupt register (ETH\_MMCTIR) are cleared.

Bit 5 **MMCRS**: MMC receive status

This bit is set high whenever an interrupt is generated in the ETH\_MMCRIR register. This bit is cleared when all the bits in this interrupt register (ETH\_MMCRIR) are cleared.

Bit 4 **MMCS**: MMC status

This bit is set high whenever any of bits 6:5 is set high. It is cleared only when both bits are low.

Bit 3 **PMTS**: PMT status

This bit is set whenever a Magic packet or Wake-on-LAN frame is received in Power-down mode (see bits 5 and 6 in the ETH\_MACPMTCSR register [Ethernet MAC PMT control and status register \(ETH\\_MACPMTCSR\)](#)). This bit is cleared when both bits[6:5], of this last register, are cleared due to a read operation to the ETH\_MACPMTCSR register.

Bits 2:0 Reserved, must be kept at reset value.

**Ethernet MAC interrupt mask register (ETH\_MACIMR)**

Address offset: 0x003C

Reset value: 0x0000 0000

The ETH\_MACIMR register bits make it possible to mask the interrupt signal due to the corresponding event in the ETH\_MACSR register.

|          |    |    |    |    |    |       |          |   |   |   |   |   |       |          |   |

|          |    |    |    |    |    | rw    |          |   |   |   |   |   | rw    |          |   |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **TSTIM**: Time stamp trigger interrupt mask

When set, this bit disables the time stamp interrupt generation.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **PMTIM**: PMT interrupt mask

When set, this bit disables the assertion of the interrupt signal due to the setting of the PMT Status bit in ETH\_MACSR.

Bits 2:0 Reserved, must be kept at reset value.

**Ethernet MAC address 0 high register (ETH\_MACA0HR)**

Address offset: 0x0040

Reset value: 0x8000 FFFF

The MAC address 0 high register holds the upper 16 bits of the 6-byte first MAC address of the station. Note that the first DA byte that is received on the MII interface corresponds to the LS Byte (bits [7:0]) of the MAC address low register. For example, if 0x1122 3344 5566 is received (0x11 is the first byte) on the MII as the destination address, then the MAC address 0 register [47:0] is compared with 0x6655 4433 2211.

Bit 31 **MO**: Always 1.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA0H**: MAC address0 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte MAC address0. This is used by the MAC for filtering for received frames and for inserting the MAC address in the transmit flow control (Pause) frames.

**Ethernet MAC address 0 low register (ETH\_MACA0LR)**

Address offset: 0x0044

Reset value: 0xFFFF FFFF

The MAC address 0 low register holds the lower 32 bits of the 6-byte first MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **MACA0L**: MAC address0 low [31:0]

This field contains the lower 32 bits of the 6-byte MAC address0. This is used by the MAC for filtering for received frames and for inserting the MAC address in the transmit flow control (Pause) frames.

**Ethernet MAC address 1 high register (ETH\_MACA1HR)**

Address offset: 0x0048

Reset value: 0x0000 FFFF

The MAC address 1 high register holds the upper 16 bits of the 6-byte second MAC address of the station.

|    |    |     |    |    |    |    |    |          |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| AE | SA | MBC |    |    |    |    |    | Reserved |    |    |    |    |    |    |    | MACA1H |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW | rW | rW  | rW | rW | rW | rW | rW |          |    |    |    |    |    |    |    | rW     | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bit 31 **AE**: Address enable

When this bit is set, the address filters use the MAC address1 for perfect filtering. When this bit is cleared, the address filters ignore the address for filtering.

Bit 30 **SA**: Source address

When this bit is set, the MAC address1[47:0] is used for comparison with the SA fields of the received frame.

When this bit is cleared, the MAC address1[47:0] is used for comparison with the DA fields of the received frame.

Bits 29:24 **MBC**: Mask byte control

These bits are mask control bits for comparison of each of the MAC address1 bytes. When they are set high, the MAC core does not compare the corresponding byte of received DA/SA with the contents of the MAC address1 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH\_MACA1HR [15:8]
- Bit 28: ETH\_MACA1HR [7:0]
- Bit 27: ETH\_MACA1LR [31:24]
- ...
- Bit 24: ETH\_MACA1LR [7:0]

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA1H**: MAC address1 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte second MAC address.

Ethernet MAC address1 low register (ETH\_MACA1LR)

Address offset: 0x004C

Reset value: 0xFFFF FFFF

The MAC address 1 low register holds the lower 32 bits of the 6-byte second MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **MACA1L**: MAC address1 low [31:0]

This field contains the lower 32 bits of the 6-byte MAC address1. The content of this field is undefined until loaded by the application after the initialization process.

Ethernet MAC address 2 high register (ETH\_MACA2HR)

Address offset: 0x0050

Reset value: 0x0000 FFFF

The MAC address 2 high register holds the upper 16 bits of the 6-byte second MAC address of the station.

|    |    |     |    |    |    |    |    |    |          |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bit 31 **AE**: Address enable

When this bit is set, the address filters use the MAC address2 for perfect filtering. When reset, the address filters ignore the address for filtering.

Bit 30 **SA**: Source address

When this bit is set, the MAC address 2 [47:0] is used for comparison with the SA fields of the received frame.

When this bit is reset, the MAC address 2 [47:0] is used for comparison with the DA fields of the received frame.

Bits 29:24 **MBC**: Mask byte control

These bits are mask control bits for comparison of each of the MAC address2 bytes. When set high, the MAC core does not compare the corresponding byte of received DA/SA with the contents of the MAC address 2 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH\_MACA2HR [15:8]
- Bit 28: ETH\_MACA2HR [7:0]
- Bit 27: ETH\_MACA2LR [31:24]
- ...
- Bit 24: ETH\_MACA2LR [7:0]

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA2H**: MAC address2 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte MAC address2.

### Ethernet MAC address 2 low register (ETH\_MACA2LR)

Address offset: 0x0054

Reset value: 0xFFFF FFFF

The MAC address 2 low register holds the lower 32 bits of the 6-byte second MAC address of the station.

| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Bits 31:0 **MACA2L**: MAC address2 low [31:0]

This field contains the lower 32 bits of the 6-byte second MAC address2. The content of this field is undefined until loaded by the application after the initialization process.

**Ethernet MAC address 3 high register (ETH\_MACA3HR)**

Address offset: 0x0058

Reset value: 0x0000 FFFF

The MAC address 3 high register holds the upper 16 bits of the 6-byte second MAC address of the station.

|    |    |     |    |    |    |    |    |    |          |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bit 31 **AE**: Address enable

When this bit is set, the address filters use the MAC address3 for perfect filtering. When this bit is cleared, the address filters ignore the address for filtering.

Bit 30 **SA**: Source address

When this bit is set, the MAC address 3 [47:0] is used for comparison with the SA fields of the received frame.

When this bit is cleared, the MAC address 3[47:0] is used for comparison with the DA fields of the received frame.

Bits 29:24 **MBC**: Mask byte control

These bits are mask control bits for comparison of each of the MAC address3 bytes. When these bits are set high, the MAC core does not compare the corresponding byte of received DA/SA with the contents of the MAC address 3 registers. Each bit controls the masking of the bytes as follows:

- Bit 29: ETH\_MACA3HR [15:8]
- Bit 28: ETH\_MACA3HR [7:0]
- Bit 27: ETH\_MACA3LR [31:24]
- ...
- Bit 24: ETH\_MACA3LR [7:0]

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **MACA3H**: MAC address3 high [47:32]

This field contains the upper 16 bits (47:32) of the 6-byte MAC address3.

**Ethernet MAC address 3 low register (ETH\_MACA3LR)**

Address offset: 0x005C

Reset value: 0xFFFF FFFF

The MAC address 3 low register holds the lower 32 bits of the 6-byte second MAC address of the station.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:0 **MACA3L**: MAC address3 low [31:0]

This field contains the lower 32 bits of the 6-byte second MAC address3. The content of this field is undefined until loaded by the application after the initialization process.

### 33.8.2 MMC register description

#### Ethernet MMC control register (ETH\_MMCCR)

Address offset: 0x0100

Reset value: 0x0000 0000

The Ethernet MMC Control register establishes the operating mode of the management counters.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |       |     |     |     |     |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|-------|-----|-----|-----|-----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5     | 4   | 3   | 2   | 1   | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   | MCFHP | MCP | MCF | ROR | CSR | CR |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   | rW    | rW  | rW  | rW  | rW  | rW |

Bits 31:6 Reserved, must be kept at reset value.

**MCFHP:** MMC counter Full-Half preset

When MCFHP is low and bit4 is set, all MMC counters get preset to almost-half value. All

Bit 5 frame-counters get preset to 0x7FFF\_FFF0 (half - 16)

When MCFHP is high and bit4 is set, all MMC counters get preset to almost-full value. All frame-counters get preset to 0xFFFF\_FFF0 (full - 16)

**MCP:** MMC counter preset

When set, all counters are initialized or preset to almost full or almost half as per

Bit 4 Bit5 above. This bit is cleared automatically after 1 clock cycle. This bit along with bit5 is useful for debugging and testing the assertion of interrupts due to MMC counter becoming half-full or full.

Bit 3 **MCF:** MMC counter freeze

When set, this bit freezes all the MMC counters to their current value. (None of the MMC counters are updated due to any transmitted or received frame until this bit is cleared to 0. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode.)

Bit 2 **ROR:** Reset on read

When this bit is set, the MMC counters is reset to zero after read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits [7:0]) is read.

Bit 1 **CSR:** Counter stop rollover

When this bit is set, the counter does not roll over to zero after it reaches the maximum value.

Bit 0 **CR:** Counter reset

When it is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

#### Ethernet MMC receive interrupt register (ETH\_MMCRIR)

Address offset: 0x0104

Reset value: 0x0000 0000

The Ethernet MMC receive interrupt register maintains the interrupts generated when receive statistic counters reach half their maximum values. (MSB of the counter is set.) It is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that

caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read in order to clear the interrupt bit.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |       |          |    |    |    |    |    |    |   |   |   |       |       |          |   |   |   |   |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RGUFS**: Received Good Unicast Frames Status

This bit is set when the received, good unicast frames, counter reaches half the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RFAES**: Received frames alignment error status

This bit is set when the received frames, with alignment error, counter reaches half the maximum value.

Bit 5 **RFCEs**: Received frames CRC error status

This bit is set when the received frames, with CRC error, counter reaches half the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

### Ethernet MMC transmit interrupt register (ETH\_MMCTIR)

Address offset: 0x0108

Reset value: 0x0000 0000

The Ethernet MMC transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values. (MSB of the counter is set.) It is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (bits [7:0]) of the respective counter must be read in order to clear the interrupt bit.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **TGFS**: Transmitted good frames status

This bit is set when the transmitted, good frames, counter reaches half the maximum value.

Bits 20:16 Reserved, must be kept at reset value.

Bit 15 **TGMSCS**: Transmitted good frames more single collision status

This bit is set when the transmitted, good frames after more than a single collision, counter reaches half the maximum value.

Bit 14 **TGFSCS**: Transmitted good frames single collision status

This bit is set when the transmitted, good frames after a single collision, counter reaches half the maximum value.

Bits 13:0 Reserved, must be kept at reset value.

### Ethernet MMC receive interrupt mask register (ETH\_MMCRIMR)

Address offset: 0x010C

Reset value: 0x0000 0000

The Ethernet MMC receive interrupt mask register maintains the masks for interrupts generated when the receive statistic counters reach half their maximum value. (MSB of the counter is set.) It is a 32-bit wide register.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17    | 16       | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6     | 5     | 4        | 3 | 2 | 1 | 0 |

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RGUFM**: Received good unicast frames mask

Setting this bit masks the interrupt when the received, good unicast frames, counter reaches half the maximum value.

Bits 16:7 Reserved, must be kept at reset value.

Bit 6 **RFAEM**: Received frames alignment error mask

Setting this bit masks the interrupt when the received frames, with alignment error, counter reaches half the maximum value.

Bit 5 **RFCEM**: Received frame CRC error mask

Setting this bit masks the interrupt when the received frames, with CRC error, counter reaches half the maximum value.

Bits 4:0 Reserved, must be kept at reset value.

**Ethernet MMC transmit interrupt mask register (ETH\_MMCTIMR)**

Address offset: 0x0110

Reset value: 0x0000 0000

The Ethernet MMC transmit interrupt mask register maintains the masks for interrupts generated when the transmit statistic counters reach half their maximum value. (MSB of the counter is set). It is a 32-bit wide register.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21   | 20       | 19 | 18 | 17 | 16 | 15 | 14      | 13     | 12       | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **TGFM**: Transmitted good frames mask

Setting this bit masks the interrupt when the transmitted, good frames, counter reaches half the maximum value.

Bits 20:16 Reserved, must be kept at reset value.

Bit 15 **TGFMSCM**: Transmitted good frames more single collision mask

Setting this bit masks the interrupt when the transmitted good frames after more than a single collision counter reaches half the maximum value.

Bit 14 **TGFSCM**: Transmitted good frames single collision mask

Setting this bit masks the interrupt when the transmitted good frames after a single collision counter reaches half the maximum value.

Bits 13:0 Reserved, must be kept at reset value.

**Ethernet MMC transmitted good frames after a single collision counter register (ETH\_MMCTGFSCCR)**

Address offset: 0x014C

Reset value: 0x0000 0000

This register contains the number of successfully transmitted frames after a single collision in Half-duplex mode.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **TSPFFMAE**: Time stamp PTP frame filtering MAC address enable

When set, this bit uses the MAC address (except for MAC address 0) to filter the PTP frames when PTP is sent directly over Ethernet.

Bits 17:16 **TSCNT**: Time stamp clock node type

The following are the available types of clock node:

- 00: Ordinary clock
- 01: Boundary clock
- 10: End-to-end transparent clock
- 11: Peer-to-peer transparent clock

Bit 15 **TSSMRME**: Time stamp snapshot for message relevant to master enable

When this bit is set, the snapshot is taken for messages relevant to the master node only.  
When this bit is cleared the snapshot is taken for messages relevant to the slave node only.  
This is valid only for the ordinary clock and boundary clock nodes.

Bit 14 **TSSEME**: Time stamp snapshot for event message enable

When this bit is set, the time stamp snapshot is taken for event messages only (SYNC, Delay\_Req, Pdelay\_Req or Pdelay\_Resp). When this bit is cleared the snapshot is taken for all other messages except for Announce, Management and Signaling.

Bit 13 **TSSIPV4FE**: Time stamp snapshot for IPv4 frames enable

When this bit is set, the time stamp snapshot is taken for IPv4 frames.

Bit 12 **TSSIPV6FE**: Time stamp snapshot for IPv6 frames enable

When this bit is set, the time stamp snapshot is taken for IPv6 frames.

Bit 11 **TSSPTPOEFE**: Time stamp snapshot for PTP over ethernet frames enable

When this bit is set, the time stamp snapshot is taken for frames which have PTP messages in Ethernet frames (PTP over Ethernet) also. By default snapshots are taken for UDP-IP Ethernet PTP packets.

Bit 10 **TSPTPPSV2E**: Time stamp PTP packet snooping for version2 format enable

When this bit is set, the PTP packets are snooped using the version 2 format. When the bit is cleared, the PTP packets are snooped using the version 1 format.

*Note: IEEE 1588 Version 1 and Version 2 formats as indicated in IEEE standard 1588-2008 (Revision of IEEE STD. 1588-2002).*

Bit 9 **TSSSR**: Time stamp subsecond rollover: digital or binary rollover control

When this bit is set, the Time stamp low register rolls over when the subsecond counter reaches the value 0x3B9A C9FF (999 999 999 in decimal), and increments the Time Stamp (high) seconds.

When this bit is cleared, the rollover value of the subsecond register reaches 0x7FFF FFFF. The subsecond increment has to be programmed correctly depending on the PTP's reference clock frequency and this bit value.

Bit 8 **TSSARFE**: Time stamp snapshot for all received frames enable

When this bit is set, the time stamp snapshot is enabled for all frames received by the core.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **TSARU**: Time stamp addend register update

When this bit is set, the Time stamp addend register's contents are updated to the PTP block for fine correction. This bit is cleared when the update is complete. This register bit must be read as zero before you can set it.

**Bit 4 TSITE:** Time stamp interrupt trigger enable

When this bit is set, a time stamp interrupt is generated when the system time becomes greater than the value written in the Target time register. When the Time stamp trigger interrupt is generated, this bit is cleared.

**Bit 3 TSSTU:** Time stamp system time update

When this bit is set, the system time is updated (added to or subtracted from) with the value specified in the Time stamp high update and Time stamp low update registers. Both the TSSTU and TSSTI bits must be read as zero before you can set this bit. Once the update is completed in hardware, this bit is cleared.

**Bit 2 TSSTI:** Time stamp system time initialize

When this bit is set, the system time is initialized (overwritten) with the value specified in the Time stamp high update and Time stamp low update registers. This bit must be read as zero before you can set it. When initialization is complete, this bit is cleared.

**Bit 1 TSFCU:** Time stamp fine or coarse update

When set, this bit indicates that the system time stamp is to be updated using the Fine Update method. When cleared, it indicates the system time stamp is to be updated using the Coarse method.

**Bit 0 TSE:** Time stamp enable

When this bit is set, time stamping is enabled for transmit and receive frames. When this bit is cleared, the time stamp function is suspended and time stamps are not added for transmit and receive frames. Because the maintained system time is suspended, you must always initialize the time stamp feature (system time) after setting this bit high.

The table below indicates the messages for which a snapshot is taken depending on the clock, enable master and enable snapshot for event message register settings.

**Table 195. Time stamp snapshot dependency on registers bits**

| <b>TSCNT<br/>(bits 17:16)</b> | <b>TSSMRME<br/>(bit 15)<sup>(1)</sup></b> | <b>TSSEME<br/>(bit 14)</b> | <b>Messages for which snapshots are taken</b>                   |
|-------------------------------|-------------------------------------------|----------------------------|-----------------------------------------------------------------|
| 00 or 01                      | X <sup>(2)</sup>                          | 0                          | SYNC, Follow_Up, Delay_Req, Delay_Resp                          |
| 00 or 01                      | 1                                         | 1                          | Delay_Req                                                       |
| 00 or 01                      | 0                                         | 1                          | SYNC                                                            |
| 10                            | N/A                                       | 0                          | SYNC, Follow_Up, Delay_Req, Delay_Resp                          |
| 10                            | N/A                                       | 1                          | SYNC, Follow_Up                                                 |
| 11                            | N/A                                       | 0                          | SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp |
| 11                            | N/A                                       | 1                          | SYNC, Pdelay_Req, Pdelay_Resp                                   |

1. N/A = not applicable.

2. X = don't care.

**Ethernet PTP subsecond increment register (ETH\_PTPSSIR)**

Address offset: 0x0704

Reset value: 0x0000 0000

This register contains the 8-bit value by which the subsecond register is incremented. In Coarse update mode (TSFCU bit in ETH\_PTPTSCR), the value in this register is added to the system time every clock cycle of HCLK. In Fine update mode, the value in this register is added to the system time whenever the accumulator gets an overflow.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |       |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | STSSI |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | rW    | rW | rW | rW | rW | rW | rW | rW |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **STSSI**: System time subsecond increment

The value programmed in this register is added to the contents of the subsecond value of the system time in every update.

For example, to achieve 20 ns accuracy, the value is:  $20 / 0.467 = \sim 43$  (or 0x2A).

**Ethernet PTP time stamp high register (ETH\_PTPTSHR)**

Address offset: 0x0708

Reset value: 0x0000 0000

This register contains the most significant (higher) 32 time bits. This read-only register contains the seconds system time value. The Time stamp high register, along with Time stamp low register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| STS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r   | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:0 **STS**: System time second

The value in this field indicates the current value in seconds of the System Time maintained by the core.

**Ethernet PTP time stamp low register (ETH\_PTPTSLR)**

Address offset: 0x070C

Reset value: 0x0000 0000

This register contains the least significant (lower) 32 time bits. This read-only register contains the subsecond system time value.

|       |      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31    | 30   | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| STPNS | STSS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|       | r    | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bit 31 **STPNS**: System time positive or negative sign

This bit indicates a positive or negative time value. When set, the bit indicates that time representation is negative. When cleared, it indicates that time representation is positive. Because the system time should always be positive, this bit is normally zero.

Bits 30:0 **STSS**: System time subseconds

The value in this field has the subsecond time representation, with 0.46 ns accuracy.

**Ethernet PTP time stamp high update register (ETH\_PTPTSHUR)**

Address offset: 0x0710

Reset value: 0x0000 0000

This register contains the most significant (higher) 32 bits of the time to be written to, added to, or subtracted from the System Time value. The Time stamp high update register, along with the Time stamp update low register, initializes or updates the system time maintained by the MAC. You have to write both of these registers before setting the TSSTI or TSSTU bits in the Time stamp control register.

|      |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TSUS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW   | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **TSUS**: Time stamp update second

The value in this field indicates the time, in seconds, to be initialized or added to the system time.

**Ethernet PTP time stamp low update register (ETH\_PTPTSLUR)**

Address offset: 0x0714

Reset value: 0x0000 0000

This register contains the least significant (lower) 32 bits of the time to be written to, added to, or subtracted from the System Time value.

|        |       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31     | 30    | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TSUPNS | TSUSS |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW     | rW    | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bit 31 **TSUPNS**: Time stamp update positive or negative sign

This bit indicates positive or negative time value. When set, the bit indicates that time representation is negative. When cleared, it indicates that time representation is positive. When TSSTI is set (system time initialization) this bit should be zero. If this bit is set when TSSTU is set, the value in the Time stamp update registers is subtracted from the system time. Otherwise it is added to the system time.

Bits 30:0 **TSUSS**: Time stamp update subseconds

The value in this field indicates the subsecond time to be initialized or added to the system time. This value has an accuracy of 0.46 ns (in other words, a value of 0x0000\_0001 is 0.46 ns).

**Ethernet PTP time stamp addend register (ETH\_PTPTSAR)**

Address offset: 0x0718

Reset value: 0x0000 0000

This register is used by the software to readjust the clock frequency linearly to match the master clock frequency. This register value is used only when the system time is configured for Fine update mode (TSFCU bit in ETH\_PTPTSCR). This register content is added to a 32-bit accumulator in every clock cycle and the system time is updated whenever the accumulator overflows.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| TSA |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW  | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **TSA**: Time stamp addend

This register indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **TSTTR**: Time stamp target time reached

When set, this bit indicates that the value of the system time is greater than or equal to the value specified in the Target time high and low registers. This bit is cleared when the ETH\_PTPTSSR register is read.

Bit 0 **TSSO**: Time stamp second overflow

When set, this bit indicates that the second value of the time stamp has overflowed beyond 0xFFFF FFFF.

### Ethernet PTP PPS control register (ETH\_PTPTPPSCR)

Address offset: 0x072C

Reset value: 0x0000 0000

This register controls the frequency of the PPS output.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |         |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---------|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3       | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | PPSFREQ |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | ro      | ro | ro | ro |

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **PPSFREQ**: PPS frequency selection

The PPS output frequency is set to  $2^{\text{PPSFREQ}}$  Hz.

0000: 1 Hz with a pulse width of 125 ms for binary rollover and, of 100 ms for digital rollover

0001: 2 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

0010: 4 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

0011: 8 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

0100: 16 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

...

1111: 32768 Hz with 50% duty cycle for binary rollover (digital rollover not recommended)

*Note: If digital rollover is used (TSSSR=1, bit 9 in ETH\_PTPTSSR), it is recommended not to use the PPS output with a frequency other than 1 Hz. Otherwise, with digital rollover, the PPS output has irregular waveforms at higher frequencies (though its average frequency is always correct during any one-second window).*

### 33.8.4 DMA register description

This section defines the bits for each DMA register. Non-32 bit accesses are allowed as long as the address is word-aligned.

#### Ethernet DMA bus mode register (ETH\_DMABMR)

Address offset: 0x1000

Reset value: 0x0002 0101

The bus mode register establishes the bus operating modes for the DMA.

|          |    |    |    |    |    |     |     |     |     |    |    |    |    |    |    |    |     |    |    |    |    |      |     |    |    |    |    |    |    |    |    |

|          |    |    |    |    | rw | rw  | rw  | rw  | rw  | rw | rw | rw | rw | rw | rw | rw | rw  | rw | rw | rw | rw |      | rw  | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **MB**: Mixed burst

When this bit is set high and the FB bit is low, the AHB master interface starts all bursts of a length greater than 16 with INCR (undefined burst). When this bit is cleared, it reverts to fixed burst transfers (INCRx and SINGLE) for burst lengths of 16 and below.

Bit 25 **AAB**: Address-aligned beats

When this bit is set high and the FB bit equals 1, the AHB interface generates all bursts aligned to the start address LS bits. If the FB bit equals 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address.

Bit 24 **FPM**: 4xPBL mode

When set high, this bit multiplies the PBL value programmed (bits [22:17] and bits [13:8]) four times. Thus the DMA transfers data in a maximum of 4, 8, 16, 32, 64 and 128 beats depending on the PBL value.

Bit 23 **USP**: Use separate PBL

When set high, it configures the RxDMA to use the value configured in bits [22:17] as PBL while the PBL value in bits [13:8] is applicable to TxDMA operations only. When this bit is cleared, the PBL value in bits [13:8] is applicable for both DMA engines.

Bits 22:17 **RDP**: Rx DMA PBL

These bits indicate the maximum number of beats to be transferred in one RxDMA transaction. This is the maximum value that is used in a single block read/write operation. The RxDMA always attempts to burst as specified in RDP each time it starts a burst transfer on the host bus. RDP can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. These bits are valid and applicable only when USP is set high.

Bit 16 **FB**: Fixed burst

This bit controls whether the AHB Master interface performs fixed burst transfers or not. When set, the AHB uses only SINGLE, INCR4, INCR8 or INCR16 during start of normal burst transfers. When reset, the AHB uses SINGLE and INCR burst transfer operations.

Bits 15:14 **PM**: Rx Tx priority ratio

**RxDMA requests are given priority over TxDMA requests in the following ratio:**

00: 1:1

01: 2:1

10: 3:1

11: 4:1

This is valid only when the DA bit is cleared.

Bits 13:8 **PBL**: Programmable burst length

These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block read/write operation. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set, this PBL value is applicable for TxDMA transactions only.

The PBL values have the following limitations:

- The maximum number of beats (PBL) possible is limited by the size of the Tx FIFO and Rx FIFO.
- The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO.
- If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered.
- Do not program out-of-range PBL values, because the system may not behave properly.

Bit 7 **EDFE**: Enhanced descriptor format enable

When this bit is set, the enhanced descriptor format is enabled and the descriptor size is increased to 32 bytes (8 words). This is required when time stamping is activated (TSE=1, ETH\_PTPTSCR bit 0) or if IPv4 checksum offload is activated (IPCO=1, ETH\_MACCCR bit 10).

Bits 6:2 **DSL**: Descriptor skip length

This bit specifies the number of words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When DSL value equals zero, the descriptor table is taken as contiguous by the DMA, in Ring mode.

Bit 1 **DA**: DMA Arbitration

0: Round-robin with Rx:Tx priority given in bits [15:14]

1: Rx has priority over Tx

Bit 0 **SR**: Software reset

When this bit is set, the MAC DMA controller resets all MAC Subsystem internal registers and logic. It is cleared automatically after the reset operation has completed in all of the core clock domains. Read a 0 value in this bit before re-programming any register of the core.

### Ethernet DMA transmit poll demand register (ETH\_DMATPDR)

Address offset: 0x1004

Reset value: 0x0000 0000

This register is used by the application to instruct the DMA to poll the transmit descriptor list. The transmit poll demand register enables the Transmit DMA to check whether or not the current descriptor is owned by DMA. The Transmit Poll Demand command is given to wake up the TxDMA if it is in Suspend mode. The TxDMA can go into Suspend mode due to an underflow error in a transmitted frame or due to the unavailability of descriptors owned by

transmit DMA. You can issue this command anytime and the TxDMA resets it once it starts re-fetching the current descriptor from host memory.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TPD |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| rw  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 TPD: Transmit poll demand

When these bits are written with any value, the DMA reads the current descriptor pointed to by the ETH\_DMACHTDR register. If that descriptor is not available (owned by Host), transmission returns to the Suspend state and ETH\_DMASR register bit 2 is asserted. If the descriptor is available, transmission resumes.

### ETHERNET DMA receive poll demand register (ETH\_DMARPDR)

Address offset: 0x1008

Reset value: 0x0000 0000

This register is used by the application to instruct the DMA to poll the receive descriptor list. The Receive poll demand register enables the receive DMA to check for new descriptors. This command is given to wake up the RxDMA from Suspend state. The RxDMA can go into Suspend state only due to the unavailability of descriptors owned by it.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RPD   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| rw_wt |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 RPD: Receive poll demand

When these bits are written with any value, the DMA reads the current descriptor pointed to by the ETH\_DMACHRDR register. If that descriptor is not available (owned by Host), reception returns to the Suspended state and ETH\_DMASR register bit 7 is not asserted. If the descriptor is available, the Receive DMA returns to active state.

### Ethernet DMA receive descriptor list address register (ETH\_DMARDLAR)

Address offset: 0x100C

Reset value: 0x0000 0000

The Receive descriptor list address register points to the start of the receive descriptor list. The descriptor lists reside in the STM32F4xx's physical memory space and must be word-aligned. The DMA internally converts it to bus-width aligned address by making the corresponding LS bits low. Writing to the ETH\_DMARDLAR register is permitted only when reception is stopped. When stopped, the ETH\_DMARDLAR register must be written to before the receive Start command is given.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| SRL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **SRL**: Start of receive list

This field contains the base address of the first descriptor in the receive descriptor list. The LSB bits [1/2/3:0] for 32/64/128-bit bus width) are internally ignored and taken as all-zero by the DMA. Hence these LSB bits are read only.

### Ethernet DMA transmit descriptor list address register (ETH\_DMATDLAR)

Address offset: 0x1010

Reset value: 0x0000 0000

The Transmit descriptor list address register points to the start of the transmit descriptor list. The descriptor lists reside in the STM32F4xx's physical memory space and must be word-aligned. The DMA internally converts it to bus-width-aligned address by taking the corresponding LSB to low. Writing to the ETH\_DMATDLAR register is permitted only when transmission has stopped. Once transmission has stopped, the ETH\_DMATDLAR register can be written before the transmission Start command is given.

|     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| STL |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW  | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **STL**: Start of transmit list

This field contains the base address of the first descriptor in the transmit descriptor list. The LSB bits [1/2/3:0] for 32/64/128-bit bus width) are internally ignored and taken as all-zero by the DMA. Hence these LSB bits are read-only.

### Ethernet DMA status register (ETH\_DMASR)

Address offset: 0x1014

Reset value: 0x0000 0000

The Status register contains all the status bits that the DMA reports to the application. The ETH\_DMASR register is usually read by the software driver during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The ETH\_DMASR register bits are not cleared when read. Writing 1 to (unreserved) bits in ETH\_DMASR register[16:0] clears them and writing 0 has no effect. Each field (bits [16:0]) can be masked by masking the appropriate bit in the ETH\_DMAIER register.

|          |    |    |    |      |          |     |    |    |     |    |    |     |    |    |     |     |     |      |          |    |    |   |     |      |      |      |    |     |     |      |      |      |    |
|----------|----|----|----|------|----------|-----|----|----|-----|----|----|-----|----|----|-----|-----|-----|------|----------|----|----|---|-----|------|------|------|----|-----|-----|------|------|------|----|
| 31       | 30 | 29 | 28 | 27   | 26       | 25  | 24 | 23 | 22  | 21 | 20 | 19  | 18 | 17 | 16  | 15  | 14  | 13   | 12       | 11 | 10 | 9 | 8   | 7    | 6    | 5    | 4  | 3   | 2   | 1    | 0    |      |    |
| Reserved |    |    |    | TSTS | Reserved | EBS |    |    | TPS |    |    | RPS |    |    | NIS | AIS | ERS | FBES | Reserved |    |    |   | ETS | RWTS | RPSS | RBUS | RS | TUS | ROS | TJTS | TBUS | TPSS | TS |
|          |    |    |    | r    |          | r   | r  | r  | r   | r  | r  | r   | r  | r  | r   | r   | r   | r    |          |    |    |   | r   | r    | r    | r    | r  | r   | r   | r    | r    | r    | r  |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **TSTS**: Time stamp trigger status

This bit indicates an interrupt event in the MAC core's Time stamp generator block. The software must read the MAC core's status register, clearing its source (bit 9), to reset this bit to 0. When this bit is high an interrupt is generated if enabled.

Bit 28 **PMTS**: PMT status

This bit indicates an event in the MAC core's PMT. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear its source to reset this bit to 0. The interrupt is generated when this bit is high if enabled.

Bit 27 **MMCS**: MMC status

This bit reflects an event in the MMC of the MAC core. The software must read the corresponding registers in the MAC core to get the exact cause of interrupt and clear the source of interrupt to make this bit as 0. The interrupt is generated when this bit is high if enabled.

Bit 26 Reserved, must be kept at reset value.

Bits 25:23 **EBS**: Error bits status

These bits indicate the type of error that caused a bus error (error response on the AHB interface). Valid only with the fatal bus error bit (ETH\_DMASR register [13]) set. This field does not generate an interrupt.

Bit 23 1 Error during data transfer by TxDMA

0 Error during data transfer by RxDMA

Bit 24 1 Error during read transfer

0 Error during write transfer

Bit 25 1 Error during descriptor access

0 Error during data buffer access

Bits 22:20 **TPS**: Transmit process state

These bits indicate the Transmit DMA FSM state. This field does not generate an interrupt.

000: Stopped; Reset or Stop Transmit Command issued

001: Running; Fetching transmit transfer descriptor

010: Running; Waiting for status

011: Running; Reading Data from host memory buffer and queuing it to transmit buffer (Tx FIFO)

100, 101: Reserved for future use

110: Suspended; Transmit descriptor unavailable or transmit buffer underflow

111: Running; Closing transmit descriptor

Bits 19:17 **RPS**: Receive process state

These bits indicate the Receive DMA FSM state. This field does not generate an interrupt.

000: Stopped: Reset or Stop Receive Command issued

001: Running: Fetching receive transfer descriptor

010: Reserved for future use

011: Running: Waiting for receive packet

100: Suspended: Receive descriptor unavailable

101: Running: Closing receive descriptor

110: Reserved for future use

111: Running: Transferring the receive packet data from receive buffer to host memory

**Bit 16 NIS:** Normal interrupt summary

The normal interrupt summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH\_DMAIER register:

- ETH\_DMASR [0]: Transmit interrupt
- ETH\_DMASR [2]: Transmit buffer unavailable
- ETH\_DMASR [6]: Receive interrupt
- ETH\_DMASR [14]: Early receive interrupt

Only unmasked bits affect the normal interrupt summary bit.

This is a sticky bit and it must be cleared (by writing a 1 to this bit) each time a corresponding bit that causes NIS to be set is cleared.

**Bit 15 AIS:** Abnormal interrupt summary

The abnormal interrupt summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH\_DMAIER register:

- ETH\_DMASR [1]: Transmit process stopped
- ETH\_DMASR [3]: Transmit jabber timeout
- ETH\_DMASR [4]: Receive FIFO overflow
- ETH\_DMASR [5]: Transmit underflow
- ETH\_DMASR [7]: Receive buffer unavailable
- ETH\_DMASR [8]: Receive process stopped
- ETH\_DMASR [9]: Receive watchdog timeout
- ETH\_DMASR [10]: Early transmit interrupt
- ETH\_DMASR [13]: Fatal bus error

Only unmasked bits affect the abnormal interrupt summary bit.

This is a sticky bit and it must be cleared each time a corresponding bit that causes AIS to be set is cleared.

**Bit 14 ERS:** Early receive status

This bit indicates that the DMA had filled the first data buffer of the packet. Receive Interrupt ETH\_DMASR [6] automatically clears this bit.

**Bit 13 FBES:** Fatal bus error status

This bit indicates that a bus error occurred, as detailed in [25:23]. When this bit is set, the corresponding DMA engine disables all its bus accesses.

Bits 12:11 Reserved, must be kept at reset value.

**Bit 10 ETS:** Early transmit status

This bit indicates that the frame to be transmitted was fully transferred to the Transmit FIFO.

**Bit 9 RWTS:** Receive watchdog timeout status

This bit is asserted when a frame with a length greater than 2 048 bytes is received.

**Bit 8 RPSS:** Receive process stopped status

This bit is asserted when the receive process enters the Stopped state.

**Bit 7 RBUS:** Receive buffer unavailable status

This bit indicates that the next descriptor in the receive list is owned by the host and cannot be acquired by the DMA. Receive process is suspended. To resume processing receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, receive process resumes when the next recognized incoming frame is received. ETH\_DMASR [7] is set only when the previous receive descriptor was owned by the DMA.

Bit 6 **RS**: Receive status

This bit indicates the completion of the frame reception. Specific frame status information has been posted in the descriptor. Reception remains in the Running state.

Bit 5 **TUS**: Transmit underflow status

This bit indicates that the transmit buffer had an underflow during frame transmission. Transmission is suspended and an underflow error TDES0[1] is set.

Bit 4 **ROS**: Receive overflow status

This bit indicates that the receive buffer had an overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].

Bit 3 **TJTS**: Transmit jabber timeout status

This bit indicates that the transmit jabber timer expired, meaning that the transmitter had been excessively active. The transmission process is aborted and placed in the Stopped state. This causes the transmit jabber timeout TDES0[14] flag to be asserted.

Bit 2 **TBUS**: Transmit buffer unavailable status

This bit indicates that the next descriptor in the transmit list is owned by the host and cannot be acquired by the DMA. Transmission is suspended. Bits [22:20] explain the transmit process state transitions. To resume processing transmit descriptors, the host should change the ownership of the bit of the descriptor and then issue a Transmit Poll Demand command.

Bit 1 **TPSS**: Transmit process stopped status

This bit is set when the transmission is stopped.

Bit 0 **TS**: Transmit status

This bit indicates that frame transmission is finished and TDES1[31] is set in the first descriptor.

**Ethernet DMA operation mode register (ETH\_DMAOMR)**

Address offset: 0x1018

Reset value: 0x0000 0000

The operation mode register establishes the Transmit and Receive operating modes and commands. The ETH\_DMAOMR register should be the last CSR to be written as part of DMA initialization.

| 31       | 30 | 29 | 28 | 27     | 26  | 25   | 24       | 23 | 22 | 21 | 20  | 19  | 18       | 17 | 16 | 15 | 14  | 13 | 12 | 11 | 10       | 9 | 8 | 7 | 6   | 5    | 4        | 3   | 2 | 1   | 0  |          |
|----------|----|----|----|--------|-----|------|----------|----|----|----|-----|-----|----------|----|----|----|-----|----|----|----|----------|---|---|---|-----|------|----------|-----|---|-----|----|----------|
| Reserved |    |    |    | DTCEFD | RSF | DFRF | Reserved |    |    |    | TSF | FTF | Reserved |    |    |    | TTC |    |    | ST | Reserved |   |   |   | FEF | FUGF | Reserved | RTC |   | OSF | SR | Reserved |
|          |    |    |    | rw     |     |      |          |    |    |    | rw  |     |          |    |    |    |     |    |    |    |          |   |   |   | rw  |      |          |     |   |     |    |          |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DTCEFD**: Dropping of TCP/IP checksum error frames disable

When this bit is set, the core does not drop frames that only have errors detected by the receive checksum offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors in the encapsulated payload only. When this bit is cleared, all error frames are dropped if the FEF bit is reset.

**Bit 25 RSF:** Receive store and forward

When this bit is set, a frame is read from the Rx FIFO after the complete frame has been written to it, ignoring RTC bits. When this bit is cleared, the Rx FIFO operates in Cut-through mode, subject to the threshold specified by the RTC bits.

**Bit 24 DFRF:** Disable flushing of received frames

When this bit is set, the RxDMA does not flush any frames due to the unavailability of receive descriptors/buffers as it does normally when this bit is cleared (see [Receive process suspended](#)).

Bits 23:22 Reserved, must be kept at reset value.

**Bit 21 TSF:** Transmit store and forward

When this bit is set, transmission starts when a full frame resides in the Transmit FIFO. When this bit is set, the TTC values specified by the ETH\_DMAOMR register bits [16:14] are ignored.

When this bit is cleared, the TTC values specified by the ETH\_DMAOMR register bits [16:14] are taken into account.

This bit should be changed only when transmission is stopped.

**Bit 20 FTF:** Flush transmit FIFO

When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO are lost/flushed. This bit is cleared internally when the flushing operation is complete. The Operation mode register should not be written to until this bit is cleared.

Bits 19:17 Reserved, must be kept at reset value.

**Bits 16:14 TTC:** Transmit threshold control

These three bits control the threshold level of the Transmit FIFO. Transmission starts when the frame size within the Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when the TSF bit (Bit 21) is cleared.

000: 64

001: 128

010: 192

011: 256

100: 40

101: 32

110: 24

111: 16

**Bit 13 ST:** Start/stop transmission

When this bit is set, transmission is placed in the Running state, and the DMA checks the transmit list at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the transmit list base address set by the ETH\_DMATDLAR register, or from the position retained when transmission was stopped previously. If the current descriptor is not owned by the DMA, transmission enters the Suspended state and the transmit buffer unavailable bit (ETH\_DMASR [2]) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting the DMA ETH\_DMATDLAR register, the DMA behavior is unpredictable.

When this bit is cleared, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The next descriptor position in the transmit list is saved, and becomes the current position when transmission is restarted. The Stop Transmission command is effective only when the transmission of the current frame is complete or when the transmission is in the Suspended state.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **FEF**: Forward error frames

When this bit is set, all frames except runt error frames are forwarded to the DMA.

When this bit is cleared, the Rx FIFO drops frames with error status (CRC error, collision error, giant frame, watchdog timeout, overflow). However, if the frame's start byte (write) pointer is already transferred to the read controller side (in Threshold mode), then the frames are not dropped. The Rx FIFO drops the error frames if that frame's start byte is not transferred (output) on the ARI bus.

Bit 6 **FUGF**: Forward undersized good frames

When this bit is set, the Rx FIFO forwards undersized frames (frames with no error and length less than 64 bytes) including pad-bytes and CRC).

When this bit is cleared, the Rx FIFO drops all frames of less than 64 bytes, unless such a frame has already been transferred due to lower value of receive threshold (e.g., RTC = 01).

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **RTC**: Receive threshold control

These two bits control the threshold level of the Receive FIFO. Transfer (request) to DMA starts when the frame size within the Receive FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are transferred automatically.

*Note: Note that value of 11 is not applicable if the configured Receive FIFO size is 128 bytes.*

*Note: These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1.*

00: 64

01: 32

10: 96

11: 128

Bit 2 **OSF**: Operate on second frame

When this bit is set, this bit instructs the DMA to process a second frame of Transmit data even before status for first frame is obtained.

Bit 1 **SR**: Start/stop receive

When this bit is set, the receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the receive list and processes incoming frames. Descriptor acquisition is attempted from the current position in the list, which is the address set by the DMA ETH\_DMARDLAR register or the position retained when the receive process was previously stopped. If no descriptor is owned by the DMA, reception is suspended and the receive buffer unavailable bit (ETH\_DMASR [7]) is set. The Start Receive command is effective only when reception has stopped. If the command was issued before setting the DMA ETH\_DMARDLAR register, the DMA behavior is unpredictable.

When this bit is cleared, RxDMA operation is stopped after the transfer of the current frame. The next descriptor position in the receive list is saved and becomes the current position when the receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or the Suspended state.

Bit 0 Reserved, must be kept at reset value.

**Ethernet DMA interrupt enable register (ETH\_DMAIER)**

Address offset: 0x101C

Reset value: 0x0000 0000

The Interrupt enable register enables the interrupts reported by ETH\_DMASR. Setting a bit to 1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16   | 15   | 14   | 13    | 12       | 11 | 10   | 9     | 8     | 7     | 6   | 5    | 4    | 3     | 2     | 1     | 0   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|------|------|-------|----------|----|------|-------|-------|-------|-----|------|------|-------|-------|-------|-----|

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16 NISE:** Normal interrupt summary enable

When this bit is set, a normal interrupt is enabled. When this bit is cleared, a normal interrupt is disabled. This bit enables the following bits:

- ETH\_DMASR [0]: Transmit Interrupt
- ETH\_DMASR [2]: Transmit buffer unavailable
- ETH\_DMASR [6]: Receive interrupt
- ETH\_DMASR [14]: Early receive interrupt

**Bit 15 AISE:** Abnormal interrupt summary enable

When this bit is set, an abnormal interrupt is enabled. When this bit is cleared, an abnormal interrupt is disabled. This bit enables the following bits:

- ETH\_DMASR [1]: Transmit process stopped
- ETH\_DMASR [3]: Transmit jabber timeout
- ETH\_DMASR [4]: Receive overflow
- ETH\_DMASR [5]: Transmit underflow
- ETH\_DMASR [7]: Receive buffer unavailable
- ETH\_DMASR [8]: Receive process stopped
- ETH\_DMASR [9]: Receive watchdog timeout
- ETH\_DMASR [10]: Early transmit interrupt
- ETH\_DMASR [13]: Fatal bus error

**Bit 14 ERIE:** Early receive interrupt enable

When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the early receive interrupt is enabled.

When this bit is cleared, the early receive interrupt is disabled.

**Bit 13 FBEIE:** Fatal bus error interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the fatal bus error interrupt is enabled.

When this bit is cleared, the fatal bus error enable interrupt is disabled.

Bits 12:11 Reserved, must be kept at reset value.

**Bit 10 ETIE:** Early transmit interrupt enable

When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register [15]), the early transmit interrupt is enabled.

When this bit is cleared, the early transmit interrupt is disabled.

- Bit 9 **RWTIE**: receive watchdog timeout interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive watchdog timeout interrupt is enabled.  
When this bit is cleared, the receive watchdog timeout interrupt is disabled.
- Bit 8 **RPSIE**: Receive process stopped interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive stopped interrupt is enabled. When this bit is cleared, the receive stopped interrupt is disabled.
- Bit 7 **RBUIE**: Receive buffer unavailable interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive buffer unavailable interrupt is enabled.  
When this bit is cleared, the receive buffer unavailable interrupt is disabled.
- Bit 6 **RIE**: Receive interrupt enable  
When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the receive interrupt is enabled.  
When this bit is cleared, the receive interrupt is disabled.
- Bit 5 **TUIE**: Underflow interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the transmit underflow interrupt is enabled.  
When this bit is cleared, the underflow interrupt is disabled.
- Bit 4 **ROIE**: Overflow interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the receive overflow interrupt is enabled.  
When this bit is cleared, the overflow interrupt is disabled.
- Bit 3 **TJTIE**: Transmit jabber timeout interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the transmit jabber timeout interrupt is enabled.  
When this bit is cleared, the transmit jabber timeout interrupt is disabled.
- Bit 2 **TBUIE**: Transmit buffer unavailable interrupt enable  
When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the transmit buffer unavailable interrupt is enabled.  
When this bit is cleared, the transmit buffer unavailable interrupt is disabled.
- Bit 1 **TPSIE**: Transmit process stopped interrupt enable  
When this bit is set with the abnormal interrupt summary enable bit (ETH\_DMAIER register[15]), the transmission stopped interrupt is enabled.  
When this bit is cleared, the transmission stopped interrupt is disabled.
- Bit 0 **TIE**: Transmit interrupt enable  
When this bit is set with the normal interrupt summary enable bit (ETH\_DMAIER register[16]), the transmit interrupt is enabled.  
When this bit is cleared, the transmit interrupt is disabled.

The Ethernet interrupt is generated only when the TSTS or PMTS bits of the DMA Status register is asserted with their corresponding interrupt are unmasked, or when the NIS/AIS Status bit is asserted and the corresponding Interrupt Enable bits (NISE/AISE) are enabled.

### Ethernet DMA missed frame and buffer overflow counter register (ETH\_DMAMFBOCR)

Address offset: 0x1020

Reset value: 0x0000 0000

The DMA maintains two counters to track the number of missed frames during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits [15:0] indicate missed frames due to the STM32F4xx buffer being unavailable (no receive descriptor was available). Bits [27:17] indicate missed frames due to Rx FIFO overflow conditions and runt frames (good frames of less than 64 bytes).

| 31       | 30 | 29 | 28   | 27   | 26   | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   | 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|----------|----|----|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Reserved |    |    | OFOC | MFA  |      |      |      |      |      |      |      |      |      |      |      | OMFC | MFC  |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
|          |    |    | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r | rc_r |

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **OFOC**: Overflow bit for FIFO overflow counter

Bits 27:17 **MFA**: Missed frames by the application

Indicates the number of frames missed by the application

Bit 16 **OMFC**: Overflow bit for missed frame counter

Bits 15:0 **MFC**: Missed frames by the controller

Indicates the number of frames missed by the Controller due to the host receive buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame.

### Ethernet DMA receive status watchdog timer register (ETH\_DMARSWTR)

Address offset: 0x1024

Reset value: 0x0000 0000

This register, when written with a non-zero value, enables the watchdog timer for the receive status (RS, ETH\_DMASR[6]).

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6 | 5 | 4 | 3  | 2  | 1  | 0  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-------|---|---|---|----|----|----|----|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   | RSWTC |   |   |   | rw | rw | rw | rw |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |       |   |   |   |    |    |    |    |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **RSWTC**: Receive status (RS) watchdog timer count

Indicates the number of HCLK clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the RxDMA completes the transfer of a frame for which the RS status bit is not set due to the setting of RDES1[31] in the corresponding descriptor. When the watchdog timer runs out, the RS bit is set and the timer is stopped. The watchdog timer is reset when the RS bit is set high due to automatic setting of RS as per RDES1[31] of any received frame.

**Ethernet DMA current host transmit descriptor register (ETH\_DMACHTDR)**

Address offset: 0x1048

Reset value: 0x0000 0000

The Current host transmit descriptor register points to the start address of the current transmit descriptor read by the DMA.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 **HTDAP**: Host transmit descriptor address pointer  
Cleared . Pointer updated by DMA during operation.

**Ethernet DMA current host receive descriptor register (ETH\_DMACHRDR)**

Address offset: 0x104C

Reset value: 0x0000 0000

The Current host receive descriptor register points to the start address of the current receive descriptor read by the DMA.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:0 **HRDAP**: Host receive descriptor address pointer  
Cleared On Reset. Pointer updated by DMA during operation.

**Ethernet DMA current host transmit buffer address register (ETH\_DMACHTBAR)**

Address offset: 0x1050

Reset value: 0x0000 0000

The Current host transmit buffer address register points to the current transmit buffer address being read by the DMA.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

## 34 USB on-the-go full-speed (OTG\_FS)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 34.1 OTG\_FS introduction

Portions Copyright (c) 2004, 2005 Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG\_FS controller.

The following acronyms are used throughout this section:

|      |                                                |
|------|------------------------------------------------|
| FS   | Full-speed                                     |
| LS   | Low-speed                                      |
| MAC  | Media access controller                        |
| OTG  | On-the-go                                      |
| PFC  | Packet FIFO controller                         |
| PHY  | Physical layer                                 |
| USB  | Universal serial bus                           |
| UTMI | USB 2.0 transceiver macrocell interface (UTMI) |

References are made to the following documents:

- USB On-The-Go Supplement, Revision 1.3
- Universal Serial Bus Revision 2.0 Specification

The OTG\_FS is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the *On-The-Go Supplement to the USB 2.0 Specification*. It can also be configured as a host-only or device-only controller, fully compliant with the *USB 2.0 Specification*. In host mode, the OTG\_FS supports full-speed (FS, 12 Mbits/s) and low-speed (LS, 1.5 Mbits/s) transfers whereas in device mode, it only supports full-speed (FS, 12 Mbits/s) transfers. The OTG\_FS supports both HNP and SRP. The only external device required is a charge pump for  $V_{BUS}$  in host mode.

## 34.2 OTG\_FS main features

The main features can be divided into three categories: general, host-mode and device-mode features.

### 34.2.1 General features

The OTG\_FS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 1.3 specification
  - Integrated support for A-B Device Identification (ID line)
  - Integrated support for host Negotiation Protocol (HNP) and Session Request Protocol (SRP)
  - It allows host to turn  $V_{BUS}$  off to conserve battery power in OTG applications
  - It supports OTG monitoring of  $V_{BUS}$  levels with internal comparators
  - It supports dynamic host-peripheral switch of role
- It is software-configurable to operate as:
  - SRP capable USB FS Peripheral (B-device)
  - SRP capable USB FS/LS host (A-device)
  - USB On-The-Go Full-Speed Dual Role device
- It supports FS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity (OTG\_FS\_SOF)
  - SOF pulse internal connection to timer2 (TIM2)
  - Configurable framing period
  - Configurable end of frame interrupt
- It includes power saving features such as system stop during USB Suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management
- It features a dedicated RAM of 1.25 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1ms) without system intervention

### 34.2.2 Host-mode features

The OTG\_FS interface main features and requirements in host-mode are the following:

- External charge pump for  $V_{BUS}$  voltage generation.
- Up to 8 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 8 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 8 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared RX FIFO, a periodic TX FIFO and a nonperiodic TX FIFO for efficient usage of the USB data RAM.

### 34.2.3 Peripheral-mode features

The OTG\_FS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 3 IN endpoints (EPs) configurable to support Bulk, Interrupt or Isochronous transfers
- 3 OUT endpoints configurable to support Bulk, Interrupt or Isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 4 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.

### 34.3 OTG\_FS functional description

Figure 386. OTG full-speed block diagram

#### 34.3.1 OTG pins

Table 197. OTG\_FS input/output pins

| Signal name | Signal type          | Description                         |
|-------------|----------------------|-------------------------------------|
| OTG_FS_DP   | Digital input/output | USB OTG D+ line                     |
| OTG_FS_DM   | Digital input/output | USB OTG D- line                     |
| OTG_FS_ID   | Digital input        | USB OTG ID                          |
| OTG_FS_VBUS | Analog input         | USB OTG VBUS                        |
| OTG_FS_SOF  | Digital output       | USB OTG Start Of Frame (visibility) |

#### 34.3.2 OTG full-speed core

The USB OTG FS receives the 48 MHz  $\pm 0.25\%$  clock from the reset and clock controller (RCC), via an external quartz. The USB clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG FS core.

The CPU reads and writes from/to the OTG FS core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in [Section 34.15: OTG\\_FS interrupts](#).

The CPU submits data over the USB by writing 32-bit words to dedicated OTG\_FS locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx-FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG\_FS addresses (pop registers). The data are then automatically retrieved from a shared Rx-FIFO configured within the 1.25 KB USB data RAM. There is one Rx-FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the full-/low-speed transceiver module within the on-chip physical layer (PHY).

### 34.3.3 Full-speed OTG PHY

The embedded full-speed OTG PHY is controlled by the OTG FS core and conveys USB control & data signals through the full-speed subset of the UTMI+ Bus (UTMIFS). It provides the physical support to USB connectivity.

The full-speed OTG PHY includes the following components:

- FS/LS transceiver module used by both host and device. It directly drives transmission and reception on the single-ended USB lines.
- integrated ID pull-up resistor used to sample the ID line for A/B device identification.
- DP/DM integrated pull-up and pull-down resistors controlled by the OTG\_FS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as  $V_{BUS}$  is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the device's role is changed via the host negotiation protocol (HNP).
- Pull-up/pull-down resistor ECN circuit. The DP pull-up consists of 2 resistors controlled separately from the OTG\_FS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows for better noise rejection and Tx/Rx signal quality.
- $V_{BUS}$  sensing comparators with hysteresis used to detect  $V_{BUS}$  Valid, A-B Session Valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the  $V_{BUS}$  supply during USB operations.
- $V_{BUS}$  pulsing method circuit used to charge/discharge  $V_{BUS}$  through resistors during the SRP (weak drive).

**Caution:** To guarantee a correct operation for the USB OTG FS peripheral, the AHB frequency should be higher than 14.2 MHz.

## 34.4 OTG dual role device (DRD)

Figure 387. OTG A-B device connection

1. External voltage regulator only needed when building a  $V_{BUS}$  powered device
2. STMP2141STR needed only if the application has to support a  $V_{BUS}$  powered device. A basic power switch can be used if 5 V are available on the application board.

### 34.4.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin (OTG\_FS\_ID). The ID line status is determined on plugging in the USB, depending on which side of the USB cable is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default Peripheral role is confirmed. In this configuration the OTG\_FS complies with the standard FSM described by section 6.8.2: On-The-Go B-device of the On-The-Go Specification Rev1.3 supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG\_FS issues an ID line status change interrupt (CIDSCHG bit in OTG\_FS\_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG\_FS complies with the standard FSM described by section 6.8.1: On-The-Go A-device of the On-The-Go Specification Rev1.3 supplement to the USB2.0.

### 34.4.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in OTG\_FS\_GUSBCFG) enables the OTG\_FS core to dynamically change its role from A-host to A-peripheral and vice-versa, or from B-Peripheral to B-host and vice-versa according to the host negotiation protocol (HNP). The current device status can be read by the combined values of the Connector ID Status bit in the Global OTG control and status register (CIDSTS bit in OTG\_FS\_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG\_FS\_GINTSTS).

The HNP program model is described in detail in [Section 34.17: OTG\\_FS programming model](#).

### 34.4.3 SRP dual role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_FS\_GUSBCFG) enables the OTG\_FS core to switch off the generation of  $V_{BUS}$  for the A-device to save power. Note that the A-device is always in charge of driving  $V_{BUS}$  regardless of the host or peripheral role of the OTG\_FS.

the SRP A/B-device program model is described in detail in [Section 34.17: OTG\\_FS programming model](#).

## 34.5 USB peripheral

This section gives the functional description of the OTG\_FS in the USB peripheral mode. The OTG\_FS works as an USB peripheral in the following circumstances:

- OTG B-Peripheral
  - OTG B-device default state if B-side of USB cable is plugged in
- OTG A-Peripheral
  - OTG A-device state after the HNP switches the OTG\_FS to its peripheral role
- B-device
  - If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG\_FS\_GUSBCFG) is cleared (see On-The-Go Rev1.3 par. 6.8.3).
- Peripheral only (see [Figure 388: USB peripheral-only connection](#))
  - The force device mode bit in the Global USB configuration register (FDMOD in OTG\_FS\_GUSBCFG) is set to 1, forcing the OTG\_FS core to work as a USB peripheral-only (see On-The-Go Rev1.3 par. 6.8.3). In this case, the ID line is ignored even if present on the USB connector.

**Note:** *To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added that generates the  $V_{DD}$  chip-supply from  $V_{BUS}$ .*

*The  $V_{BUS}$  pin can be freed by disabling the  $V_{BUS}$  sensing option. This is done by setting the NOVBUSSENS bit in the OTG\_FS\_GCCFG register. In this case the  $V_{BUS}$  is considered internally to be always at  $V_{BUS}$  valid level (5 V).*

Figure 388. USB peripheral-only connection

1. Use a regulator to build a bus-powered device.

### 34.5.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG\_FS\_GUSBCFG) enables the OTG\_FS to support the session request protocol (SRP). In this way, it allows the remote A-device to save power by switching off  $V_{BUS}$  while the USB session is suspended.

The SRP peripheral mode program model is described in detail in the [B-device session request protocol](#) section.

### 34.5.2 Peripheral states

#### Powered state

The  $V_{BUS}$  input detects the B-Session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 par9.1). The OTG\_FS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG\_FS\_GINTSTS) to notify the powered state.

The  $V_{BUS}$  input also ensures that valid  $V_{BUS}$  levels are supplied by the host during USB operations. If a drop in  $V_{BUS}$  below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG\_FS automatically disconnects and the session end detected (SEDET bit in OTG\_FS\_GOTGINT) interrupt is generated to notify that the OTG\_FS has exited the powered state.

In the powered state, the OTG\_FS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG\_FS\_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG\_FS\_GINTSTS) is generated and the OTG\_FS enters the Default state.

### Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG\_FS\_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

### Default state

In the Default state the OTG\_FS expects to receive a SET\_ADDRESS command from the host. No other USB operation is possible. When a valid SET\_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG\_FS\_DCFG). The OTG\_FS then enters the address state and is ready to answer host transactions at the configured USB address.

### Suspended state

The OTG\_FS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG\_FS\_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG\_FS\_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG\_FS\_DSTS) and the OTG\_FS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG\_FS\_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG\_FS\_GINTSTS) is generated and the device suspend bit is automatically cleared.

## 34.5.3 Peripheral endpoints

The OTG\_FS core instantiates the following USB endpoints:

- Control endpoint 0:
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Proper control (OTG\_FS\_DIEPCTL0/OTG\_FS\_DOEPCTL0), transfer configuration (OTG\_FS\_DIEPTSIZ0/OTG\_FS\_DOEPSIZ0), and status-interrupt (OTG\_FS\_DIEPINTx/OTG\_FS\_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints
- 3 IN endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has proper control (OTG\_FS\_DIEPCTLx), transfer configuration (OTG\_FS\_DIEPTSIZx), and status-interrupt (OTG\_FS\_DIEPINTx) registers
  - The Device IN endpoints common interrupt mask register (OTG\_FS\_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG\_FS\_GINTSTS), asserted when there is at least one isochronous IN endpoint

on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_FS\_GINTSTS/EOPF).

- 3 OUT endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a proper control (OTG\_FS\_DOEPCTLx), transfer configuration (OTG\_FS\_DOEPSIZx) and status-interrupt (OTG\_FS\_DOEPINTx) register
  - Device Out endpoints common interrupt mask register (OTG\_FS\_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOOUT bit in OTG\_FS\_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_FS\_GINTSTS/EOPF).

### Endpoint control

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (DIEPCTLx/DOEPCTLx):
  - Endpoint enable/disable
  - Endpoint activate in current configuration
  - Program USB transfer type (isochronous, bulk, interrupt)
  - Program supported packet size
  - Program Tx-FIFO number associated with the IN endpoint
  - Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - Optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - Optionally program the STALL bit to always stall host tokens to that endpoint
  - Optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

### Endpoint transfer

The device endpoint-x transfer size registers (DIEPTSIZx/DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG FS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets that constitute the overall transfer size

## Endpoint status/interrupt

The device endpoint-x interrupt registers (DIEPINTx/DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in the core interrupt register (OEPINT bit in OTG\_FS\_GINTSTS or IEPINT bit in OTG\_FS\_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG\_FS\_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINTE and GINTSTS registers

The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- Setup stage has been done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx-FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- Babble error condition has been detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets were received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet has been dropped, without generating an interrupt

## 34.6 USB host

This section gives the functional description of the OTG\_FS in the USB host mode. The OTG\_FS works as a USB host in the following circumstances:

- OTG A-host
  - OTG A-device default state when the A-side of the USB cable is plugged in
- OTG B-host
  - OTG B-device after HNP switching to the host role
- A-device
  - If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG\_FS\_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only (see [Figure 389: USB host-only connection](#)).
  - The force host mode bit in the global USB configuration register (FHMODO bit in OTG\_FS\_GUSBCFG) forces the OTG\_FS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

**Note:** *On-chip 5 V  $V_{BUS}$  generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive*

the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.

The  $V_{BUS}$  input ensures that valid  $V_{BUS}$  levels are supplied by the charge pump during USB operations while the charge pump overcurrent output can be input to any GPIO pin configured to generate port interrupts. The overcurrent ISR must promptly disable the  $V_{BUS}$  generation.

The  $V_{BUS}$  pin can be freed by disabling the  $V_{BUS}$  sensing option. This is done by setting the `NOVBUSSENS` bit in the `OTG_FS_GCCFG` register. In this case the  $V_{BUS}$  is considered internally to be always at  $V_{BUS}$  valid level (5 V).

**Figure 389. USB host-only connection**

1. STMP2141STR needed only if the application has to support a  $V_{BUS}$  powered device. A basic power switch can be used if 5 V are available on the application board.
2.  $V_{DD}$  range is between 2 V and 3.6 V.

### 34.6.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in `OTG_FS_GUSBCFG`). With the SRP feature enabled, the host can save power by switching off the  $V_{BUS}$  power while the USB session is suspended.

The SRP host mode program model is described in detail in the [A-device session request protocol](#) section.

### 34.6.2 USB host states

#### Host port power

On-chip 5 V  $V_{BUS}$  generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output. When the application decides to power on  $V_{BUS}$  using the chosen GPIO, it must also set the port power bit in the host port control and status register (PPWR bit in `OTG_FS_HPRT`).

### **V<sub>BUS</sub> valid**

When HNP or SRP is enabled the VBUS sensing pin (PA9) pin should be connected to V<sub>BUS</sub>. The V<sub>BUS</sub> input ensures that valid V<sub>BUS</sub> levels are supplied by the charge pump during USB operations. Any unforeseen V<sub>BUS</sub> voltage drop below the V<sub>BUS</sub> valid threshold (4.25 V) leads to an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG\_FS\_GOTGINT). The application is then required to remove the V<sub>BUS</sub> power and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin (PA9) should not be connected to V<sub>BUS</sub>. This pin can be used as GPIO.

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the V<sub>BUS</sub> generation and clear the port power bit.

### **Host detection of a peripheral connection**

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG\_FS does not detect any bus connection until V<sub>BUS</sub> is no longer sensed at a valid level (5 V). When V<sub>BUS</sub> is at a valid level and a remote B-device is attached, the OTG\_FS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG\_FS\_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG\_FS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG\_FS\_HPRT).

### **Host detection of peripheral a disconnection**

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG\_FS\_GINTSTS).

### **Host enumeration**

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

Before starting to drive a USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG\_FS\_GOTGINT), which indicates that the bus is stable again after the electrical debounce caused by the attachment of a pull-up resistor on DP (FS) or DM (LS).

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG\_FS\_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG\_FS\_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG\_FS\_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

### Host suspend

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG\_FS\_HPRT). The OTG\_FS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device's initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG\_FS\_GINTSTS) is generated upon detection of a remote wake-up signaling, the port resume bit in the host port control and status register (PRES bit in OTG\_FS\_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.

### 34.6.3 Host channels

The OTG\_FS core instantiates 8 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 8 transfer requests at the same time. If more than 8 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of proper control (HCCHARx), transfer configuration (HCTSIZx) and status/interrupt (HCINTx) registers with associated mask (HCINTMSKx) registers.

#### Host channel control

- The following host channel controls are available to the application through the host channel-x characteristics register (HCCHARx):
  - Channel enable/disable
  - Program the FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames

#### Host channel transfer

The host channel transfer size registers (HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint

is enabled the packet count field is read-only as the OTG FS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

### Host channel status/interrupt

The host channel-x interrupt register (HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG\_FS\_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (HCAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HCAINT and GINTSTS registers. The mask bits for each interrupt source of each channel are also available in the OTG\_FS\_HCINTMSK-x register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - fraMe overrun
  - dAta toggle error

## 34.6.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG\_FS\_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG HS core is fully

responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (HPTXSTS) and nonperiodic transmit FIFO and queue status register (HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx-FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of 8 pending periodic transactions plus 8 pending nonperiodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the PTXQSAV bits in the OTG\_FS\_HNPTXSTS register or NPTQSAV bits in the OTG\_FS\_HNPTXSTS register.

## 34.7 SOF trigger

Figure 390. SOF connectivity

The OTG FS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature.

Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.

### 34.7.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt

is generated at any start of frame (SOF bit in OTH\_FS\_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

An SOF pulse signal, generated at any SOF starting token and with a width of 20 HCLK cycles, can be made available externally on the OTG\_FS\_SOF pin using the SOFOUTEN bit in the global control and configuration register. The SOF pulse is also internally connected to the input trigger of timer 2 (TIM2), so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse. The TIM2 connection is enabled through the ITR1\_RMP bits of TIM2\_OR register.

### 34.7.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTH\_FS\_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG\_FS\_DSTS). An SOF pulse signal with a width of 20 HCLK cycles is also generated and can be made available externally on the OTG\_FS\_SOF pin by using the SOF output enable bit in the global control and configuration register (SOFOUTEN bit in OTG\_FS\_GCCFG). The SOF pulse signal is also internally connected to the TIM2 input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse. The TIM2 connection is enabled through the ITR1\_RMP bits of the TIM2 option register (TIM2\_OR).

The end of periodic frame interrupt (GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG\_FS\_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

## 34.8 OTG low-power modes

[Table 198](#) below defines the STM32 low power modes and their compatibility with the OTG.

**Table 198. Compatibility of STM32 low power modes with the OTG**

| Mode    | Description                                                                                                 | USB compatibility                        |
|---------|-------------------------------------------------------------------------------------------------------------|------------------------------------------|
| Run     | MCU fully active                                                                                            | Required when USB not in suspend state.  |
| Sleep   | USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.                | Available while USB is in suspend state. |
| Stop    | USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept <sup>(1)</sup> . | Available while USB is in suspend state. |
| Standby | Powered-down. The peripheral must be reinitialized after exiting Standby mode.                              | Not compatible with USB applications.    |

1. Within Stop mode there are different possible settings. Some restrictions may also exist, please refer to [Section 5: Power controller \(PWR\)](#) to understand which (if any) restrictions apply when using OTG.

The power consumption of the OTG PHY is controlled by three bits in the general core configuration register:

- PHY power down (GCCFG/PWRDWN)  
It switches on/off the full-speed transceiver module of the PHY. It must be preliminarily set to allow any USB operation.
- A- $V_{BUS}$  sensing enable (GCCFG/VBUSASEN)  
It switches on/off the  $V_{BUS}$  comparators associated with A-device operations. It must be set when in A-device (USB host) mode and during HNP.
- B- $V_{BUS}$  sensing enable (GCCFG/VBUSASEN)  
It switches on/off the  $V_{BUS}$  comparators associated with B-device operations. It must be set when in B-device (USB peripheral) mode and during HNP.

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- Stop PHY clock (STPPCLK bit in OTG\_FS\_PCGCCTL)  
When setting the stop PHY clock bit in the clock gating control register, most of the 48 MHz clock domain internal to the OTG full-speed core is switched off by clock gating. The dynamic power consumption due to the USB clock switching activity is cut even if the 48 MHz clock input is kept running by the application  
Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.
- Gate HCLK (GATEHCLK bit in OTG\_FS\_PCGCCTL)  
When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG\_FS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.
- USB system stop  
When the OTG\_FS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).  
The OTG\_FS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG\_FS core.

## 34.9 Dynamic update of the OTG\_FS\_HFIR register

The USB core embeds a dynamic trimming capability of SOF framing period in host mode allowing to synchronize an external device with the SOF frames.

When the OTG\_FS\_HFIR register is changed within a current SOF frame, the SOF period correction is applied in the next frame as described in [Figure 391](#).

Figure 391. Updating OTG\_FS\_HFIR dynamically

### 34.10 USB data FIFOs

The USB system features 1.25 Kbyte of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG\_FS core organizes RAM space into Tx-FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device's role. In peripheral mode an additional Tx-FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.

## 34.11 Peripheral FIFO architecture

Figure 392. Device-mode FIFO address mapping and AHB FIFO access mapping

### 34.11.1 Peripheral Rx FIFO

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx-FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO Size register (GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG FS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx-FIFO non-empty interrupt (RXFLVL bit in OTG\_FS\_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.

### 34.11.2 Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the non periodic transmit FIFO size register (OTG\_FS\_TX0FSIZ) for IN endpoint0 and the device IN endpoint transmit FIFOx registers (DIEPTXFx) for IN endpoint-x.

## 34.12 Host FIFO architecture

**Figure 393. Host-mode FIFO address mapping and AHB FIFO access mapping**

### 34.12.1 Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (GRXFSIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG FS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.

### 34.12.2 Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size (HPTXFSIZ/HNPTXFSIZ) register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG FS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG\_FS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG\_FS\_GINTSTS) as long as the periodic Tx-FIFO is half or completely empty, depending on the value of the periodic Tx-FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG\_FS\_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (HPTXSTS) can be read to know how much space is available in both.

OTG\_FS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG\_FS\_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG\_FS\_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (HNPTXSTS) can be read to know how much space is available in both.

## 34.13 FIFO RAM allocation

### 34.13.1 Device mode

**Receive FIFO RAM allocation:** the application should allocate RAM for SETUP Packets: 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data. One location is to be allocated for Global OUT NAK. Status information is written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{Largest Packet Size} / 4) + 1$  must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two  $(\text{Largest Packet Size} / 4) + 1$  spaces must be allocated to receive back-to-back packets. Typically, two  $(\text{Largest Packet Size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. Typically, one location for each OUT endpoint is recommended.

**Transmit FIFO RAM allocation:** the minimum RAM space required for each IN Endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

*Note:* More space allocated in the transmit IN Endpoint FIFO results in better performance on the USB.

### 34.13.2 Host mode

#### Receive FIFO RAM allocation

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{Largest Packet Size} / 4) + 1$  must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two  $(\text{Largest Packet Size} / 4) + 1$  spaces must be allocated to receive back-to-back packets. Typically, two  $(\text{Largest Packet Size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

#### Transmit FIFO RAM allocation

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two Largest Packet Sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one Isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

*Note:* More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.

### 34.14 USB system performance

Best USB and system performance is achieved owing to the large RAM buffers, the highly configurable FIFO sizes, the quick 32-bit FIFO access through AHB push/pop registers and, especially, the advanced FIFO control mechanism. Indeed, this mechanism allows the OTG\_FS to fill in the available RAM space at best regardless of the current USB sequence. With these features:

- The application gains good margins to calibrate its intervention in order to optimize the CPU bandwidth usage:
  - It can accumulate large amounts of transmission data in advance compared to when they are effectively sent over the USB
  - It benefits of a large time margin to download data from the single receive FIFO
- The USB Core is able to maintain its full operating rate, that is to provide maximum full-speed bandwidth with a great margin of autonomy versus application intervention:
  - It has a large reserve of transmission data at its disposal to autonomously manage the sending of data over the USB

- It has a lot of empty space available in the receive buffer to autonomously fill it in with the data coming from the USB

As the OTG\_FS core is able to fill in the 1.25 Kbyte RAM buffer very efficiently, and as 1.25 Kbyte of transmit/receive data is more than enough to cover a full speed frame, the USB system is able to withstand the maximum full-speed data rate for up to one USB frame (1 ms) without any CPU intervention.

### 34.15 OTG\_FS interrupts

When the OTG\_FS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the Core interrupt register (MMIS bit in the OTG\_FS\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 394* shows the interrupt hierarchy.

Figure 394. Interrupt hierarchy

MSv36921V3

## 34.16 OTG\_FS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG\_FS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG\_FS registers must be accessed by words (32 bits).

CSRs are classified as follows:

- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the Core global, Power and clock-gating, Data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG\_FS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the Core interrupt register (MMIS bit in the OTG\_FS\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

### 34.16.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

**Figure 395. CSR memory map**

### Global CSR map

These registers are available in both host and device modes.

**Table 199. Core global control and status registers (CSRs)**

| Acronym        | Address offset | Register name                                                                    |

### Data FIFO (DFIFO) access register map

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Table 202. Data FIFO (DFIFO) access register map

| FIFO access register section                                                                                              | Address range | Access |
|---------------------------------------------------------------------------------------------------------------------------|---------------|--------|

1. Where x is 3 in device mode and 7 in host mode.

### Power and clock gating CSR map

There is a single register for power and clock gating. It is available in both host and device modes.

**Table 203. Power and clock gating control and status registers**

| Register name                           | Acronym        | Offset address: 0xE00–0xFFFF |
|-----------------------------------------|----------------|------------------------------|
| Power and clock gating control register | OTG_FS_PCGCCTL | 0xE00-0xE04                  |
| Reserved                                | -              | 0xE05–0xFFFF                 |

### 34.16.2 OTG\_FS global registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

#### OTG\_FS control and status register (OTG\_FS\_GOTGCTL)

Address offset: 0x000

Reset value: 0x0001 0000

The OTG\_FS\_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19    | 18    | 17   | 16     | 15       | 14 | 13 | 12 | 11    | 10    | 9    | 8      | 7        | 6 | 5 | 4 | 3   | 2      | 1 | 0 |
|----------|----|----|----|----|----|----|----|----|----|----|----|-------|-------|------|--------|----------|----|----|----|-------|-------|------|--------|----------|---|---|---|-----|--------|---|---|
| Reserved |    |    |    |    |    |    |    |    |    |    |    | BSVLD | ASVLD | DBCT | CIDSTS | Reserved |    |    |    | DHPNP | HSHNP | HNPQ | HNGSCS | Reserved |   |   |   | SRQ | SRQSCS |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    | r     | r     | r    | r      |          |    |    |    | rw    | rw    | rw   | r      |          |   |   |   | rw  | r      |   |   |

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **BSVLD**: B-session valid

Indicates the device mode transceiver status.

0: B-session is not valid.

1: B-session is valid.

In OTG mode, you can use this bit to determine if the device is connected or disconnected.

*Note:* Only accessible in device mode.

Bit 18 **ASVLD**: A-session valid

Indicates the host mode transceiver status.

0: A-session is not valid

1: A-session is valid

*Note:* Only accessible in host mode.

Bit 17 **DBCT**: Long/short debounce time

Indicates the debounce time of a detected connection.

0: Long debounce time, used for physical connections (100 ms + 2.5  $\mu$ s)

1: Short debounce time, used for soft connections (2.5  $\mu$ s)

*Note:* Only accessible in host mode.

Bit 16 **CIDSTS**: Connector ID status

Indicates the connector ID status on a connect event.

0: The OTG\_FS controller is in A-device mode

1: The OTG\_FS controller is in B-device mode

*Note:* Accessible in both device and host modes.

Bits 15:12 Reserved, must be kept at reset value.

**Bit 11 DHNPEN:** Device HNP enabled

The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.

0: HNP is not enabled in the application

1: HNP is enabled in the application

*Note:* Only accessible in device mode.

**Bit 10 HSHNPEN:** host set HNP enable

The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.

0: Host Set HNP is not enabled

1: Host Set HNP is enabled

*Note:* Only accessible in host mode.

**Bit 9 HNPRQ:** HNP request

The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG\_FS\_GOTGINT register (HNSSCHG bit in OTG\_FS\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

0: No HNP request

1: HNP request

*Note:* Only accessible in device mode.

**Bit 8 HNGSCS:** Host negotiation success

The core sets this bit when host negotiation is successful. The core clears this bit when the HNP Request (HNPRQ) bit in this register is set.

0: Host negotiation failure

1: Host negotiation success

*Note:* Only accessible in device mode.

Bits 7:2 Reserved, must be kept at reset value.

**Bit 1 SRQ:** Session request

The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG\_FS\_GOTGINT register (HNSSCHG bit in OTG\_FS\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

If you use the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until  $V_{BUS}$  discharges to 0.2 V, after the B-Session Valid bit in this register (BSVLD bit in OTG\_FS\_GOTGCTL) is cleared.

0: No session request

1: Session request

*Note:* Only accessible in device mode.

**Bit 0 SRQSCS:** Session request success

The core sets this bit when a session request initiation is successful.

0: Session request failure

1: Session request success

*Note:* Only accessible in device mode.

**OTG\_FS interrupt register (OTG\_FS\_GOTGINT)**

Address offset: 0x04

Reset value: 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

|          |    |    |    |    |    |    |    |    |    |    |    |        |         |        |          |    |    |    |    |    |    |   |         |         |          |   |   |   |   |       |      |
|----------|----|----|----|----|----|----|----|----|----|----|----|--------|---------|--------|----------|----|----|----|----|----|----|---|---------|---------|----------|---|---|---|---|-------|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19     | 18      | 17     | 16       | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8       | 7       | 6        | 5 | 4 | 3 | 2 | 1     | 0    |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | DBCDNE | ADTOCHG | HNGDET | Reserved |    |    |    |    |    |    |   | HNSSCHG | SRSSCHG | Reserved |   |   |   |   | SEDET | Res. |
|          |    |    |    |    |    |    |    |    |    |    |    | rc_w1  | rc_w1   | rc_w1  |          |    |    |    |    |    |    |   | rc_w1   | rc_w1   |          |   |   |   |   | rc_w1 |      |

Bits 31:20 Reserved, must be kept at reset value.

**Bit 19 DBCDNE:** Debounce done

The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the OTG\_FS\_GUSBCFG register (HNPCAP bit or SRPCAP bit in OTG\_FS\_GUSBCFG, respectively).

*Note:* Only accessible in host mode.

**Bit 18 ADTOCHG:** A-device timeout change

The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note:* Accessible in both device and host modes.

**Bit 17 HNGDET:** Host negotiation detected

The core sets this bit when it detects a host negotiation request on the USB.

*Note:* Accessible in both device and host modes.

Bits 16:10 Reserved, must be kept at reset value.

**Bit 9 HNSSCHG:** Host negotiation success status change

The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG\_FS\_GOTGCTL register (HNGSCS in OTG\_FS\_GOTGCTL) to check for success or failure.

*Note:* Accessible in both device and host modes.

Bits 7:3 Reserved, must be kept at reset value.

**Bit 8 SRSSCHG:** Session request success status change

The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG\_FS\_GOTGCTL register (SRQSCS bit in OTG\_FS\_GOTGCTL) to check for success or failure.

*Note:* Accessible in both device and host modes.

**Bit 2 SEDET:** Session end detected

The core sets this bit to indicate that the level of the voltage on  $V_{BUS}$  is no longer valid for a B-Peripheral session when  $V_{BUS} < 0.8$  V.

Bits 1:0 Reserved, must be kept at reset value.

**OTG\_FS AHB configuration register (OTG\_FS\_GAHBCFG)**

Address offset: 0x008

Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |          |         |          |   |   |         |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|----------|---------|----------|---|---|---------|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8        | 7       | 6        | 5 | 4 | 3       | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   | PTXFELVL | TXFELVL | Reserved |   |   | GINTMSK |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   | rw       | rw      |          |   |   | rw      |   |   |   |

Bits 31:9 Reserved, must be kept at reset value.

**Bit 8 PTXFELVL:** Periodic Tx FIFO empty level

Indicates when the periodic Tx FIFO empty interrupt bit in the OTG\_FS\_GINTSTS register (PTXFE bit in OTG\_FS\_GINTSTS) is triggered.

0: PTXFE (in OTG\_FS\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty  
 1: PTXFE (in OTG\_FS\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

*Note: Only accessible in host mode.*

**Bit 7 TXFELVL:** Tx FIFO empty level

In device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG\_FS\_DIEPINTx) is triggered.

0: the TXFE (in OTG\_FS\_DIEPINTx) interrupt indicates that the IN Endpoint Tx FIFO is half empty

1: the TXFE (in OTG\_FS\_DIEPINTx) interrupt indicates that the IN Endpoint Tx FIFO is completely empty

In host mode, this bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG\_FS\_GINTSTS) is triggered:

0: the NPTXFE (in OTG\_FS\_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty

1: the NPTXFE (in OTG\_FS\_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty

Bits 6:1 Reserved, must be kept at reset value.

**Bit 0 GINTMSK:** Global interrupt mask

The application uses this bit to mask or unmask the interrupt line assertion to itself.

Irrespective of this bit's setting, the interrupt status registers are updated by the core.

0: Mask the interrupt assertion to the application.

1: Unmask the interrupt assertion to the application.

*Note: Accessible in both device and host modes.*

**OTG\_FS USB configuration register (OTG\_FS\_GUSBCFG)**

Address offset: 0x00C

Reset value: 0x0000 0A40

This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

| 31     | 30    | 29    | 28       | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13   | 12 | 11         | 10     | 9    | 8      | 7        | 6     | 5 | 4 | 3 | 2 | 1 | 0 |

| CTXPKT | FDMOD | FHMOD | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    | TRDT |    | HNPCA<br>P | SRPCAP | Res. | PHYSEL | Reserved | TOTAL |   |   |   |   |   |   |
| rw     | rw    | rw    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw   | rw | rw         | r      |      | rw     |          |       |   |   |   |   |   |   |

**Bit 31 CTXPKT:** Corrupt Tx packet

This bit is for debug purposes only. Never set this bit to 1.

*Note: Accessible in both device and host modes.***Bit 30 FDMOD:** Force device mode

Writing a 1 to this bit forces the core to device mode irrespective of the OTG\_FS\_ID input pin.

0: Normal mode

1: Force device mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both device and host modes.***Bit 29 FHMOD:** Force host mode

Writing a 1 to this bit forces the core to host mode irrespective of the OTG\_FS\_ID input pin.

0: Normal mode

1: Force host mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both device and host modes.***Bits 28:14** Reserved, must be kept at reset value.**Bits 13:10 TRDT:** USB turnaround time

These bits allow setting the turnaround time in PHY clocks. They must be configured according to [Table 204: TRDT values](#), depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the Data FIFO.

*Note: Only accessible in device mode.***Bit 9 HNPCAP:** HNP-capable

The application uses this bit to control the OTG\_FS controller's HNP capabilities.

0: HNP capability is not enabled.

1: HNP capability is enabled.

*Note: Accessible in both device and host modes.*

Bit 8 **SRPCAP**: SRP-capable

The application uses this bit to control the OTG\_FS controller's SRP capabilities. If the core operates as a non-SRP-capable

B-device, it cannot request the connected A-device (host) to activate  $V_{BUS}$  and start a session.

0: SRP capability is not enabled.

1: SRP capability is enabled.

*Note: Accessible in both device and host modes.*

## Bit 7 Reserved, must be kept at reset value.

Bit 6 **PHYSEL**: Full speed serial transceiver select

This bit is always 1 with read-only access.

## Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 **TOTAL**: FS timeout calibration

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Table 204. TRDT values

| AHB frequency range (MHz) |      | TRDT minimum value |
|---------------------------|------|--------------------|
| Min.                      | Max  |                    |
| 14.2                      | 15   | 0xF                |

**OTG\_FS reset register (OTG\_FS\_GRSTCTL)**

Address offset: 0x010

Reset value: 0x8000 0000

The application uses this register to reset various hardware features inside the core.

|        |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |   |         |         |          |       |       |       |   |   |   |

**Bit 31 AHBIDL:** AHB master idle

Indicates that the AHB master state machine is in the Idle condition.

*Note: Accessible in both device and host modes.*

Bits 30:11 Reserved, must be kept at reset value.

**Bits 10:6 TXFNUM:** TxFIFO number

This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit.

00000:

- Non-periodic TxFIFO flush in host mode
- Tx FIFO 0 flush in device mode

00001:

- Periodic TxFIFO flush in host mode
- TXFIFO 1 flush in device mode

00010: TXFIFO 2 flush in device mode

...

00101: TXFIFO 15 flush in device mode

10000: Flush all the transmit FIFOs in device or host mode.

*Note: Accessible in both device and host modes.***Bit 5 TXFFLSH:** TxFIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers:

Read—NAK Effective Interrupt ensures the core is not reading from the FIFO

Write—AHBIDL bit in OTG\_FS\_GRSTCTL ensures the core is not writing anything to the FIFO.

*Note: Accessible in both device and host modes.***Bit 4 RXFFLSH:** RxFIFO flush

The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note: Accessible in both device and host modes.*

Bit 3 Reserved, must be kept at reset value.

**Bit 2 FCRST:** Host frame counter reset

The application writes this bit to reset the frame number counter inside the core. When the frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.

*Note:* Only accessible in host mode.

**Bit 1 HSRST:** HCLK soft reset

The application uses this bit to flush the control logic in the AHB Clock domain. Only AHB Clock Domain pipelines are reset.

FIFOs are not flushed with this bit.

All state machines in the AHB clock domain are reset to the Idle state after terminating the transactions on the AHB, following the protocol.

CSR control bits used by the AHB clock domain state machines are cleared.

To clear this interrupt, status mask bits that control the interrupt status and are generated by the AHB clock domain state machine are cleared.

Because interrupt status bits are not cleared, the application can get the status of any core events that occurred after it set this bit.

This is a self-clearing bit that the core clears after all necessary logic is reset in the core. This can take several clocks, depending on the core's current state.

*Note:* Accessible in both device and host modes.

**Bit 0 CSRST:** Core soft reset

Resets the HCLK and PCLK domains as follows:

Clears the interrupts and all the CSR register bits except for the following bits:

- RSTPDMODL bit in OTG\_FS\_PCGCCTL
- GAYEHCLK bit in OTG\_FS\_PCGCCTL
- PWRCLMP bit in OTG\_FS\_PCGCCTL
- STPPCLK bit in OTG\_FS\_PCGCCTL
- FSLSPCS bit in OTG\_FS\_HCFG
- DSPD bit in OTG\_FS\_DCFG

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.

The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when you dynamically change the PHY selection bits in the above listed USB configuration registers. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note:* Accessible in both device and host modes.

**OTG\_FS core interrupt register (OTG\_FS\_GINTSTS)**

Address offset: 0x014

Reset value: 0x0400 0020

This register interrupts the application for system-level events in the current mode (device mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc\_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG\_FS\_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

| 31     | 30     | 29      | 28      | 27       | 26    | 25    | 24      | 23       | 22                 | 21      | 20     | 19     | 18       | 17 | 16 | 15    | 14      | 13      | 12     | 11      | 10    | 9        | 8 | 7 | 6        | 5        | 4      | 3      | 2     | 1      | 0     |      |  |  |  |  |  |  |  |  |

Bit 31 **WKUPINT**: Resume/remote wake-up detected interrupt

In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wake-up is detected on the USB.

*Note: Accessible in both device and host modes.*

Bit 30 **SRQINT**: Session request/new session detected interrupt

In host mode, this interrupt is asserted when a session request is detected from the device. In device mode, this interrupt is asserted when  $V_{BUS}$  is in the valid range for a B-peripheral device. Accessible in both device and host modes.

Bit 29 **DISCINT**: Disconnect detected interrupt

Asserted when a device disconnect is detected.

*Note: Only accessible in host mode.*

Bit 28 **CIDSCHG**: Connector ID status change

The core sets this bit when there is a change in connector ID status.

*Note: Accessible in both device and host modes.*

Bit 27 Reserved, must be kept at reset value.

Bit 26 **PTXFE**: Periodic Tx FIFO empty

Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG\_FS\_GAHBCFG register (PTXFELVL bit in OTG\_FS\_GAHBCFG).

*Note: Only accessible in host mode.*

**Bit 25 HCINT:** Host channels interrupt

The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG\_FS\_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG\_FS\_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG\_FS\_HCINTx register to clear this bit.

*Note: Only accessible in host mode.*

**Bit 24 HPRTINT:** Host port interrupt

The core sets this bit to indicate a change in port status of one of the OTG\_FS controller ports in host mode. The application must read the OTG\_FS\_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_FS\_HPRT register to clear this bit.

*Note: Only accessible in host mode.*

Bits 23:22 Reserved, must be kept at reset value.

**Bit 21 IPXFR:** Incomplete periodic transfer

In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

**INCOMPISOOUT:** Incomplete isochronous OUT transfer

In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

**Bit 20 IISOXFR:** Incomplete isochronous IN transfer

The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*

**Bit 19 OEPINT:** OUT endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG\_FS\_DAIN register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG\_FS\_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_FS\_DOEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

**Bit 18 IEPINT:** IN endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG\_FS\_DAIN register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG\_FS\_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_FS\_DIEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16 Reserved, must be kept at reset value.

**Bit 15 EOPF:** End of periodic frame interrupt

Indicates that the period specified in the periodic frame interval field of the OTG\_FS\_DCFG register (PFIVL bit in OTG\_FS\_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

- Bit 14 **ISOODRP**: Isochronous OUT packet dropped interrupt  
 The core sets this bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.  
*Note: Only accessible in device mode.*
- Bit 13 **ENUMDNE**: Enumeration done  
 The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG\_FS\_DSTS register to obtain the enumerated speed.  
*Note: Only accessible in device mode.*
- Bit 12 **USBRST**: USB reset  
 The core sets this bit to indicate that a reset is detected on the USB.  
*Note: Only accessible in device mode.*
- Bit 11 **USBSUSP**: USB suspend  
 The core sets this bit to indicate that a suspend was detected on the USB. The core enters the Suspended state when there is no activity on the data lines for a period of 3 ms.  
*Note: Only accessible in device mode.*
- Bit 10 **ESUSP**: Early suspend  
 The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.  
*Note: Only accessible in device mode.*
- Bits 9:8 Reserved, must be kept at reset value.
- Bit 7 **GONAKEFF**: Global OUT NAK effective  
 Indicates that the Set global OUT NAK bit in the OTG\_FS\_DCTL register (SGONAK bit in OTG\_FS\_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG\_FS\_DCTL register (CGONAK bit in OTG\_FS\_DCTL).  
*Note: Only accessible in device mode.*
- Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective  
 Indicates that the Set global non-periodic IN NAK bit in the OTG\_FS\_DCTL register (SGINAK bit in OTG\_FS\_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG\_FS\_DCTL register (CGINAK bit in OTG\_FS\_DCTL).  
 This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.  
*Note: Only accessible in device mode.*
- Bit 5 **NPTXFE**: Non-periodic TxFIFO empty  
 This interrupt is asserted when the non-periodic TxFIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic TxFIFO empty level bit in the OTG\_FS\_GAHBCFG register (TXFELVL bit in OTG\_FS\_GAHBCFG).  
*Note: Accessible in host mode only.*
- Bit 4 **RXFLVL**: RxFIFO non-empty  
 Indicates that there is at least one packet pending to be read from the RxFIFO.  
*Note: Accessible in both host and device modes.*

**Bit 3 SOF:** Start of frame

In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.

In device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: Accessible in both host and device modes.*

**Bit 2 OTGINT:** OTG interrupt

The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (OTG\_FS\_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_FS\_GOTGINT register to clear this bit.

*Note: Accessible in both host and device modes.*

**Bit 1 MMIS:** Mode mismatch interrupt

The core sets this bit when the application is trying to access:

- A host mode register, when the core is operating in device mode
- A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note: Accessible in both host and device modes.*

**Bit 0 CMOD:** Current mode of operation

Indicates the current mode.

0: Device mode

1: Host mode

*Note: Accessible in both host and device modes.*

**OTG\_FS interrupt mask register (OTG\_FS\_GINTMSK)**

Address offset: 0x018

Reset value: 0x0000 0000

This register works with the Core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the Core Interrupt (OTG\_FS\_GINTSTS) register bit corresponding to that interrupt is still set.

| 31   | 30    | 29      | 28       | 27       | 26     | 25   | 24    | 23       | 22              | 21       | 20     | 19     | 18       | 17    | 16       | 15       | 14     | 13       | 12     | 11       | 10        | 9         | 8       | 7       | 6    | 5      | 4     | 3        | 2  | 1 | 0 |

0: Masked interrupt  
1: Unmasked interrupt  
*Note: Accessible in both device and host modes.*
- Bit 1 **MMISM**: Mode mismatch interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note: Accessible in both device and host modes.*
- Bit 0 Reserved, must be kept at reset value.

## OTG\_FS Receive status debug read/OTG status read and pop registers (OTG\_FS\_GRXSTSR/OTG\_FS\_GRXSTSP)

Address offset for Read: 0x01C

Address offset for Pop: 0x020

Reset value: 0x0000 0000

A read to the Receive status debug read register returns the contents of the top of the Receive FIFO. A read to the Receive status read and pop register additionally pops the top data entry out of the RxFIFO.

The receive status contents must be interpreted differently in host and device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the Receive Status FIFO when the Receive FIFO non-empty bit of the Core interrupt register (RXFLVL bit in OTG\_FS\_GINTSTS) is asserted.

### Host mode

|          |    |    |    |    |    |    |    |    |    |    |        |    |      |    |      |    |    |    |    |    |    |   |       |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|--------|----|------|----|------|----|----|----|----|----|----|---|-------|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19 | 18   | 17 | 16   | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8     | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

|          |    |    |    |    |    |    |    |    |    |    | r      |    | r    |    | r    |    |    |    |    |    |    |   | r     |   |   |   |   |   |   |   |   |

Bits 31:21 **Reserved**, must be kept at reset value.

Bits 20:17 **PKTSTS**: Packet status

Indicates the status of the received packet

0010: IN data packet received

0011: IN transfer completed (triggers an interrupt)

0101: Data toggle error (triggers an interrupt)

0111: Channel halted (triggers an interrupt)

Others: Reserved

Bits 16:15 **DPID**: Data PID

Indicates the Data PID of the received packet

00: DATA0

10: DATA1

01: DATA2

11: MDATA

Bits 14:4 **BCNT**: Byte count

Indicates the byte count of the received IN data packet.

Bits 3:0 **CHNUM**: Channel number

Indicates the channel number to which the current received packet belongs.

**Device mode**

|          |    |    |    |    |    |    |        |    |        |    |      |      |    |    |    |    |    |    |    |    |    |       |   |   |   |   |   |   |   |   |   |

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:21 **FRMNUM**: Frame number

This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS**: Packet status

Indicates the status of the received packet

0001: Global OUT NAK (triggers an interrupt)

0010: OUT data packet received

0011: OUT transfer completed (triggers an interrupt)

0100: SETUP transaction completed (triggers an interrupt)

0110: SETUP data packet received

Others: Reserved

Bits 16:15 **DPID**: Data PID

Indicates the Data PID of the received OUT data packet

00: DATA0

10: DATA1

01: DATA2

11: MDATA

Bits 14:4 **BCNT**: Byte count

Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM**: Endpoint number

Indicates the endpoint number to which the current received packet belongs.

**OTG\_FS Receive FIFO size register (OTG\_FS\_GRXFSIZ)**

Address offset: 0x024

Reset value: 0x0000 0200

The application can program the RAM size that must be allocated to the RxFIFO.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RXFD**: RxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 256

The power-on reset value of this register is specified as the largest Rx data FIFO depth.

### OTG\_FS Host non-periodic transmit FIFO size register (OTG\_FS\_HNPTXFSIZ)/Endpoint 0 Transmit FIFO size (OTG\_FS\_DIEPTXF0)

Address offset: 0x028

Reset value: 0x0000 0200

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

| rw           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw             |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

#### Host mode

Bits 31:16 **NPTXFD**: Non-periodic TxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 256

Bits 15:0 **NPTXFSA**: Non-periodic transmit RAM start address

This field contains the memory start address for non-periodic transmit FIFO RAM.

#### Device mode

Bits 31:16 **TX0FD**: Endpoint 0 TxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 256

Bits 15:0 **TX0FSA**: Endpoint 0 transmit RAM start address

This field contains the memory start address for the endpoint 0 transmit FIFO RAM.

### OTG\_FS non-periodic transmit FIFO/queue status register (OTG\_FS\_HNPTXSTS)

Address offset: 0x02C

Reset value: 0x0008 0200

**Note:** *In Device mode, this register is not valid.*

This read-only register contains the free space information for the non-periodic TxFIFO and the non-periodic transmit request queue.

|          |          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |          |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30       | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22       | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14       | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

|          | r        |    |    |    |    |    |    |    | r        |    |    |    |    |    |    |    | r        |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

- Bit 31 Reserved, must be kept at reset value.
- Bits 30:24 **NPTXQTOP**: Top of the non-periodic transmit request queue  
Entry in the non-periodic Tx request queue that is currently being processed by the MAC.  
Bits 30:27: Channel/endpoint number  
Bits 26:25:  
– 00: IN/OUT token  
– 01: Zero-length transmit packet (device IN/host OUT)  
– 11: Channel halt command  
Bit 24: Terminate (last entry for selected channel/endpoint)
- Bits 23:16 **NPTQXSAV**: Non-periodic transmit request queue space available  
Indicates the amount of free space available in the non-periodic transmit request queue.  
This queue holds both IN and OUT requests in host mode. Device mode has only IN requests.  
00: Non-periodic transmit request queue is full  
01: 1 location available  
10: 2 locations available  
bxn: n locations available ( $0 \leq n \leq 8$ )  
Others: Reserved
- Bits 15:0 **NPTXFSAV**: Non-periodic TxFIFO space available  
Indicates the amount of free space available in the non-periodic TxFIFO.  
Values are in terms of 32-bit words.  
00: Non-periodic TxFIFO is full  
01: 1 word available  
10: 2 words available  
0xn: n words available (where  $0 \leq n \leq 256$ )  
Others: Reserved

OTG\_FS general core configuration register (OTG\_FS\_GCCFG)

Address offset: 0x038  
Reset value: 0x0000 XXXX

|          |    |    |    |    |    |    |    |    |    |            |          |          |          |          |         |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

|          |    |    |    |    |    |    |    |    |    | rw         | rw       | rw       | rw       |          | rw      |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |            |          |          |          |          |         |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **NOVBUSSENS**:  $V_{BUS}$  sensing disable option

When this bit is set,  $V_{BUS}$  is considered internally to be always at  $V_{BUS}$  valid level (5 V). This option removes the need for a dedicated  $V_{BUS}$  pad, and leave this pad free to be used for other purposes such as a shared functionality.  $V_{BUS}$  connection can be remapped on another general purpose input pad and monitored by software.

This option is only suitable for host-only or device-only applications.

0:  $V_{BUS}$  sensing available by hardware

1:  $V_{BUS}$  sensing not available by hardware.

Bit 20 **SOFOUTEN**: SOF output enable

0: SOF pulse not available on PAD (OTG\_FS\_SOF)

1: SOF pulse available on PAD (OTG\_FS\_SOF)

Bit 19 **VBUSSEN**: Enable the  $V_{BUS}$  sensing “B” device

0:  $V_{BUS}$  sensing “B” disabled

1:  $V_{BUS}$  sensing “B” enabled

Bit 18 **VBUSASEN**: Enable the  $V_{BUS}$  sensing “A” device

0:  $V_{BUS}$  sensing “A” disabled

1:  $V_{BUS}$  sensing “A” enabled

Bit 17 Reserved, must be kept at reset value.

Bit 16 **PWRDWN**: Power down

Used to activate the transceiver in transmission/reception

0: Power down active

1: Power down deactivated (“Transceiver active”)

Bits 15:0 Reserved, must be kept at reset value.

### OTG\_FS core ID register (OTG\_FS\_CID)

Address offset: 0x03C

Reset value: 0x0000 1200

This is a register containing the Product ID as reset value.

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:16 **PTXFD**: Host periodic TxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Bits 15:0 **PTXSA**: Host periodic TxFIFO start address

The power-on reset value of this register is the sum of the largest Rx data FIFO depth and largest non-periodic Tx data FIFO depth.

**OTG\_FS device IN endpoint transmit FIFO size register (OTG\_FS\_DIEPTXFx)  
(x = 1..3, where x is the FIFO\_number)**

Address offset: 0x104 + 0x04 \* (x -1)

Reset value: 0x0200 0200

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| r        | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r        | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 **INEPTXFD**: IN endpoint TxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

The power-on reset value of this register is specified as the largest IN endpoint FIFO number depth.

Bits 15:0 **INEPTXSA**: IN endpoint FIFOx transmit RAM start address

This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.

### 34.16.3 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:

### OTG\_FS Host configuration register (OTG\_FS\_HCFG)

Address offset: 0x400

Reset value: 0x0000 0000

This register configures the core after power-on. Do not make changes to this register after initializing the host.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |       |         |   |  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|-------|---------|---|--|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2     | 1       | 0 |  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   | FSLSS | FSLSPCS |   |  |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   | r     |         |   |  |

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support

The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

1: FS/LS-only, even if the connected device can support HS (read-only)

Bits 1:0 **FSLSPCS**: FS/LS PHY clock select

When the core is in FS host mode

01: PHY clock is running at 48 MHz

Others: Reserved

When the core is in LS host mode

00: Reserved

### 01: Select 48 MHz PHY clock frequency

10: Select 6 MHz PHY clock frequency

11: Reserved

*Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).*

### OTG\_FS Host frame interval register (OTG\_FS\_HFIR)

Address offset: 0x404

Reset value: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG FS controller has enumerated.

[illegible]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **FRIVL**: Frame interval

The value that the application programs to this field specifies the interval between two consecutive SOFs (FS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the Port enable bit of the host port control and status register (PENA bit in OTG\_FS\_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY Clock Select field of the host configuration register (FSLSPCS in OTG\_FS\_HCFG). Do not change the value of this field after the initial configuration.

– Frame interval = 1 ms × (FRIVL - 1)

### OTG\_FS Host frame number/frame time remaining register (OTG\_FS\_HFNUM)

Address offset: 0x408

Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| FTREM |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | FRNUM |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r     | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r     | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 **FTREM**: Frame time remaining

Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0 **FRNUM**: Frame number

This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.

### OTG\_FS\_Host periodic transmit FIFO/queue status register (OTG\_FS\_HPTXSTS)

Address offset: 0x410

Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

|         |    |    |    |    |    |    |    |         |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|---------|----|----|----|----|----|----|----|---------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23      | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PTXQTOP |    |    |    |    |    |    |    | PTXQSAV |    |    |    |    |    |    |    | PTXFSAVL |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r       | r  | r  | r  | r  | r  | r  | r  | r       | r  | r  | r  | r  | r  | r  | r  | r        | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

**Bits 31:24 PTXQTOP:** Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

Bit 31: Odd/Even frame

- 0: send in even frame
- 1: send in odd frame

Bits 30:27: Channel/endpoint number

Bits 26:25: Type

- 00: IN/OUT
- 01: Zero-length packet
- 11: Disable channel command

Bit 24: Terminate (last entry for the selected channel/endpoint)

**Bits 23:16 PTXQSAV:** Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.

00: Periodic transmit request queue is full

01: 1 location available

10: 2 locations available

bxn: n locations available ( $0 \leq n \leq 8$ )

Others: Reserved

**Bits 15:0 PTXFSAVL:** Periodic transmit data FIFO space available

Indicates the number of free locations available to be written to in the periodic Tx FIFO.

Values are in terms of 32-bit words

0000: Periodic Tx FIFO is full

0001: 1 word available

0010: 2 words available

bxn: n words available (where  $0 \leq n \leq \text{PTXFD}$ )

Others: Reserved

**OTG\_FS Host all channels interrupt register (OTG\_FS\_HAINT)**

Address offset: 0x414

Reset value: 0x0000 000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the Core interrupt register (HCINT bit in OTG\_FS\_GINTSTS). This is shown in [Figure 394](#). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | HAINT |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r     | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINT:** Channel interrupts

One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15

**OTG\_FS Host all channels interrupt mask register (OTG\_FS\_HAINTMSK)**

Address offset: 0x418

Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | HAINTM |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r/w    | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINTM**: Channel interrupt mask

0: Masked interrupt

1: Unmasked interrupt

One bit per channel: Bit 0 for channel 0, bit 15 for channel 15

**OTG\_FS Host port control and status register (OTG\_FS\_HPRT)**

Address offset: 0x440

Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in [Figure 394](#). The rc\_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG\_FS\_GINTSTS). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc\_w1 bits, the application must write a 1 to the bit to clear the interrupt.

|          |    |    |    |    |    |    |    |    |    |    |    |    |      |    |       |    |    |    |      |       |    |          |      |       |      |         |      |         |       |       |       |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|------|----|-------|----|----|----|------|-------|----|----------|------|-------|------|---------|------|---------|-------|-------|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18   | 17 | 16    | 15 | 14 | 13 | 12   | 11    | 10 | 9        | 8    | 7     | 6    | 5       | 4    | 3       | 2     | 1     | 0     |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | PSPD |    | PTCTL |    |    |    | PPWR | PLSTS |    | Reserved | PRST | PSUSP | PRES | POCCHNG | POCA | PENCHNG | PENA  | PCDET | PCSTS |
|          |    |    |    |    |    |    |    |    |    |    |    |    | r    | r  | rw    | rw | rw | rw | rw   | r     | r  |          | rw   | rs    | rw   | rc_w1   | r    | rc_w1   | rc_w0 | rc_w1 | r     |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **PSPD**: Port speed

Indicates the speed of the device attached to this port.

01: Full speed

10: Low speed

11: Reserved

**Bits 16:13 PTCTL:** Port test control

The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.

0000: Test mode disabled

0001: Test\_J mode

0010: Test\_K mode

0011: Test\_SE0\_NAK mode

0100: Test\_Packet mode

0101: Test\_Force\_Enable

Others: Reserved

**Bit 12 PPWR:** Port power

The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.

0: Power off

1: Power on

**Bits 11:10 PLSTS:** Port line status

Indicates the current logic level USB data lines

Bit 10: Logic level of OTG\_FS\_DP

Bit 11: Logic level of OTG\_FS\_DM

**Bit 9** Reserved, must be kept at reset value.

**Bit 8 PRST:** Port reset

When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.

0: Port not in reset

1: Port in reset

The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.

**Bit 7 PSUSP:** Port suspend

The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the Port clock stop bit, which asserts the suspend input pin of the PHY.

The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the Port reset bit or Port resume bit in this register or the Resume/remote wake-up detected interrupt bit or Disconnect detected interrupt bit in the Core interrupt register (WKUINT or DISCINT in OTG\_FS\_GINTSTS, respectively).

0: Port not in Suspend mode

1: Port in Suspend mode

**Bit 6 PRES:** Port resume

The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.

If the core detects a USB remote wake-up sequence, as indicated by the Port resume/remote wake-up detected interrupt bit of the Core interrupt register (WKUINT bit in OTG\_FS\_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.

0: No resume driven

1: Resume driven

Bit 5 **POCCHNG**: Port overcurrent change

The core sets this bit when the status of the Port overcurrent active bit (bit 4) in this register changes.

Bit 4 **POCA**: Port overcurrent active

Indicates the overcurrent condition of the port.

0: No overcurrent condition

1: Overcurrent condition

Bit 3 **PENCHNG**: Port enable/disable change

The core sets this bit when the status of the Port enable bit 2 in this register changes.

Bit 2 **PENA**: Port enable

A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.

0: Port disabled

1: Port enabled

Bit 1 **PCDET**: Port connect detected

The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the Core interrupt register (HPRTINT bit in OTG\_FS\_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status

0: No device is attached to the port

1: A device is attached to the port

### OTG\_FS Host channel-x characteristics register (OTG\_FS\_HCCHARx) (x = 0..7, where x = Channel\_number)

Address offset: 0x500 + 0x20 \* x

Reset value: 0x0000 0000

| 31    | 30    | 29     | 28  | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20   | 19 | 18    | 17 | 16    | 15       | 14    | 13    | 12 | 11 | 10 | 9  | 8     | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |  |
|-------|-------|--------|-----|----|----|----|----|----|----|----|------|----|-------|----|-------|----------|-------|-------|----|----|----|----|-------|----|----|----|----|----|----|----|----|--|
| CHENA | CHDIS | ODDFRM | DAD |    |    |    |    |    |    |    | MCNT |    | EPTYP |    | LSDEV | Reserved | EPDIR | EPNUM |    |    |    |    | MPSIZ |    |    |    |    |    |    |    |    |  |
| rs    | rs    | rw     | rw  | rw | rw | rw | rw | rw | rw | rw | rw   | rw | rw    | rw | rw    |          | rw    | rw    | rw | rw | rw | rw | rw    | rw | rw | rw | rw | rw | rw | rw | rw |  |

Bit 31 **CHENA**: Channel enable

This field is set by the application and cleared by the OTG host.

0: Channel disabled

1: Channel enabled

Bit 30 **CHDIS**: Channel disable

The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29 **ODDFRM**: Odd frame

This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.

0: Even frame

1: Odd frame

Bits 28:22 **DAD**: Device address

This field selects the specific device serving as the data source or sink.

Bits 21:20 **MCNT**: Multicount

This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used

00: Reserved. This field yields undefined results

01: 1 transaction

10: 2 transactions per frame to be issued for this endpoint

11: 3 transactions per frame to be issued for this endpoint

*Note: This field must be set to at least 01.*

Bits 19:18 **EPTYP**: Endpoint type

Indicates the transfer type selected.

00: Control

01: Isochronous

10: Bulk

11: Interrupt

Bit 17 **LSDEV**: Low-speed device

This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR**: Endpoint direction

Indicates whether the transaction is IN or OUT.

0: OUT

1: IN

Bits 14:11 **EPNUM**: Endpoint number

Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ**: Maximum packet size

Indicates the maximum packet size of the associated endpoint.

### OTG\_FS Host channel-x interrupt register (OTG\_FS\_HCINTx) (x = 0..7, where x = Channel\_number)

Address offset:  $0x508 + 0x20 * x$

Reset value: 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in [Figure 394](#). The application must read this register when the host channels interrupt bit in the Core interrupt register (HCINT bit in OTG\_FS\_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG\_FS\_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_FS\_HAINT and OTG\_FS\_GINTSTS registers.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10    | 9     | 8     | 7     | 6        | 5     | 4     | 3     | 2        | 1     | 0    |

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERR**: Data toggle error

Bit 9 **FRMOR**: Frame overrun

Bit 8 **BBERR**: Babble error

Bit 7 **TXERR**: Transaction error

Indicates one of the following errors occurred on the USB.

CRC check failure

Timeout

Bit stuff error

False EOP

Bit 6 Reserved, must be kept at reset value.

Bit 5 **ACK**: ACK response received/transmitted interrupt

Bit 4 **NAK**: NAK response received interrupt

Bit 3 **STALL**: STALL response received interrupt

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CHH**: Channel halted

Indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.

Bit 0 **XFRC**: Transfer completed

Transfer completed normally without any errors.

### OTG\_FS Host channel-x interrupt mask register (OTG\_FS\_HCINTMSKx) (x = 0..7, where x = Channel\_number)

Address offset: 0x50C + 0x20 \* x

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10     | 9      | 8      | 7      | 6        | 5    | 4    | 3      | 2        | 1    | 0     |

| Reserved | DPID |    | PKTCNT |    |    |    |    |    |    |    |    |    |    | XFRSIZ |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
|          |      |    |        |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
| rW       | rW   | rW | rW     | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW     | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |   |

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **DPID**: Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

00: DATA0  
01: DATA2  
10: DATA1  
11: MDATA (non-control)/SETUP (control)

Bits 28:19 **PKTCNT**: Packet count

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0 **XFRSIZ**: Transfer size

For an OUT, this field is the number of data bytes the host sends during the transfer.

For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

### 34.16.4 Device-mode registers

#### OTG\_FS device configuration register (OTG\_FS\_DCFG)

Address offset: 0x800

Reset value: 0x0220 0000

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |     |    |   |   |   |   |   |          |          |    |      |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|-----|----|---|---|---|---|---|----------|----------|----|------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12    | 11  | 10 | 9 | 8 | 7 | 6 | 5 | 4        | 3        | 2  | 1    | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | PFIVL | DAD |    |   |   |   |   |   | Reserved | NZLSOHSK |    | DSPD |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw    |     |    |   |   |   |   |   |          | rw       | rw | rw   | rw |

Bits 31:13 **Reserved**, must be kept at reset value.

Bits 12:11 **PFIVL**: Periodic frame interval

Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.

00: 80% of the frame interval

01: 85% of the frame interval

10: 90% of the frame interval

11: 95% of the frame interval

Bits 10:4 **DAD**: Device address

The application must program this field after every SetAddress control command.

Bit 3 **Reserved**, must be kept at reset value.

Bit 2 **NZLSOHSK**: Non-zero-length status OUT handshake

The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's Status stage.

1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.

0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the Device endpoint control register.

Bits 1:0 **DSPD**: Device speed

Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.

00: Reserved

01: Reserved

10: Reserved

11: Full speed (USB 1.1 transceiver clock is 48 MHz)

**OTG\_FS device control register (OTG\_FS\_DCTL)**

Address offset: 0x804

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |        |        |        |        |      |    |    |        |        |      |        |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|--------|--------|--------|--------|------|----|----|--------|--------|------|--------|

| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | POPRGDNE | CGONAK | SGONAK | CGINAK | SGINAK | TCTL |    |    | GONSTS | GINSTS | SDIS | RWUSIG |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RW       | W      | W      | W      | W      | RW   | RW | RW | r      | r      | RW   | RW     |

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **POPRGDNE**: Power-on programming done

The application uses this bit to indicate that register programming is completed after a wake-up from power down mode.

Bit 10 **CGONAK**: Clear global OUT NAK

Writing 1 to this field clears the Global OUT NAK.

Bit 9 **SGONAK**: Set global OUT NAK

Writing 1 to this field sets the Global OUT NAK.

The application uses this bit to send a NAK handshake on all OUT endpoints.

The application must set this bit only after making sure that the Global OUT NAK effective bit in the Core interrupt register (GONAKEFF bit in OTG\_FS\_GINTSTS) is cleared.

Bit 8 **CGINAK**: Clear global IN NAK

Writing 1 to this field clears the Global IN NAK.

Bit 7 **SGINAK**: Set global IN NAK

Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints.

The application must set this bit only after making sure that the Global IN NAK effective bit in the Core interrupt register (GINAKEFF bit in OTG\_FS\_GINTSTS) is cleared.

Bits 6:4 **TCTL**: Test control

000: Test mode disabled

001: Test\_J mode

010: Test\_K mode

011: Test\_SE0\_NAK mode

100: Test\_Packet mode

101: Test\_Force\_Enable

Others: Reserved

Bit 3 **GONSTS**: Global OUT NAK status

0: A handshake is sent based on the FIFO Status and the NAK and STALL bit settings.

1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.

Bit 2 **GINSTS**: Global IN NAK status

0: A handshake is sent out based on the data availability in the transmit FIFO.

1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1 **SDIS**: Soft disconnect

The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.

0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.

1: The core generates a device disconnect event to the USB host.

Bit 0 **RWUSIG**: Remote wake-up signaling

When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the Suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.

[Table 205](#) contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

**Table 205. Minimum duration for soft disconnect**

| Operating speed | Device state                                    | Minimum duration   |
|-----------------|-------------------------------------------------|--------------------|
| Full speed      | Suspended                                       | 1 ms + 2.5 $\mu$ s |
| Full speed      | Idle                                            | 2.5 $\mu$ s        |
| Full speed      | Not Idle or Suspended (Performing transactions) | 2.5 $\mu$ s        |

**OTG\_FS device status register (OTG\_FS\_DSTS)**

Address offset: 0x808

Reset value: 0x0000 0010

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the device all interrupts (OTG\_FS\_DAIN) register.

|          |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |          |    |   |   |      |         |   |         |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|----------|----|---|---|------|---------|---|---------|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21    | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11       | 10 | 9 | 8 | 7    | 6       | 5 | 4       | 3 | 2 | 1 | 0 |   |   |
| Reserved |    |    |    |    |    |    |    |    |    | FNSOF |    |    |    |    |    |    |    |    |    | Reserved |    |   |   | EERR | ENUMSPD |   | SUSPSTS |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |          |    |   |   |      |         |   |         |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    | r     | r  | r  | r  | r  | r  | r  | r  | r  | r  | r        | r  | r | r | r    | r       |   |         |   |   | r | r | r | r |

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:8 **FNSOF**: Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **EERR**: Erratic error

The core sets this bit to report any erratic errors.

Due to erratic errors, the OTG\_FS controller goes into Suspended state and an interrupt is generated to the application with Early suspend bit of the OTG\_FS\_GINTSTS register (ESUSP bit in OTG\_FS\_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD**: Enumerated speed

Indicates the speed at which the OTG\_FS controller has come up after speed detection through a chirp sequence.

01: Reserved

10: Reserved

11: Full speed (PHY clock is running at 48 MHz)

Others: reserved

Bit 0 **SUSPSTS**: Suspend status

In device mode, this bit is set as long as a Suspend condition is detected on the USB. The core enters the Suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:

- When there is an activity on the USB data lines
- When the application writes to the Remote wake-up signaling bit in the OTG\_FS\_DCTL register (RWUSIG bit in OTG\_FS\_DCTL).

### OTG\_FS device IN endpoint common interrupt mask register (OTG\_FS\_DIEPMSK)

Address offset: 0x810

Reset value: 0x0000 0000

This register works with each of the OTG\_FS\_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG\_FS\_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17   | 16       | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6      | 5      | 4         | 3   | 2        | 1    | 0     |

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |      |          |    |    |    |    |    |    |   |   |   |        |        |           |     |          |      |       |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |      |          |    |    |    |    |    |    |   |   |   |        |        |           |     |          |      |       |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |      |          |    |    |    |    |    |    |   |   |   |        |        |           |     |          |      |       |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAKM**: NAK interrupt mask

0: Masked interrupt

1: Unmasked interrupt

Bits 12:7 Reserved, must be kept at reset value.

Bit 6 **INENEM**: IN endpoint NAK effective mask

0: Masked interrupt

1: Unmasked interrupt

Bit 5 **INEPNMM**: IN token received with EP mismatch mask

0: Masked interrupt

1: Unmasked interrupt

Bit 4 **ITTXFEMSK**: IN token received when TxFIFO empty mask

0: Masked interrupt

1: Unmasked interrupt

Bit 3 **TOM**: Timeout condition mask (Non-isochronous endpoints)

0: Masked interrupt

1: Unmasked interrupt

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDM**: Endpoint disabled interrupt mask

0: Masked interrupt

1: Unmasked interrupt

Bit 0 **XFRM**: Transfer completed interrupt mask

0: Masked interrupt

1: Unmasked interrupt

### OTG\_FS device OUT endpoint common interrupt mask register (OTG\_FS\_DOEPMASK)

Address offset: 0x814

Reset value: 0x0000 0000

This register works with each of the OTG\_FS\_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG\_FS\_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |       |          |            |          |           |        |       |          |      |      |    |    |    |

## OTG\_FS device all endpoints interrupt register (OTG\_FS\_DAIN)

Address offset: 0x818

Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a OTG\_FS\_DAIN register interrupts the application using the Device OUT endpoints interrupt bit or Device IN endpoints interrupt bit of the OTG\_FS\_GINTSTS register (OEPINT or IEPINT in OTG\_FS\_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-x interrupt register (OTG\_FS\_DIEPINTx/OTG\_FS\_DOEPINTx).

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| OEPINT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | IEPINT |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r      | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 **OEPINT**: OUT endpoint interrupt bits

One bit per OUT endpoint:

Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.

Bits 15:0 **IEPINT**: IN endpoint interrupt bits

One bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 3 for endpoint 3.

**OTG\_FS all endpoints interrupt mask register (OTG\_FS\_DAINMSK)**

Address offset: 0x81C

Reset value: 0x0000 0000

The OTG\_FS\_DAINMSK register works with the Device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the OTG\_FS\_DAIN register bit corresponding to that interrupt is still set.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INEPTXFEM**: IN EP Tx FIFO empty interrupt mask bits

These bits act as mask bits for OTG\_FS\_DIEPINTx.

TXFE interrupt one bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 3 for IN endpoint 3

0: Masked interrupt

1: Unmasked interrupt

### OTG\_FS device control IN endpoint 0 control register (OTG\_FS\_DIEPCTL0)

Address offset: 0x900

Reset value: 0x0000 0000

This section describes the OTG\_FS\_DIEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

|       |    |       |    |          |    |    |    |      |      |        |    |    |    |       |          |    |       |    |        |          |    |        |          |   |   |   |   |   |   |   |   |  |  |  |       |  |

- Bit 31 **EPENA**: Endpoint enable  
The application sets this bit to start transmitting data on the endpoint 0.  
The core clears this bit before setting any of the following interrupts on this endpoint:
- Endpoint disabled
  - Transfer completed
- Bit 30 **EPDIS**: Endpoint disable  
The application sets this bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint disabled interrupt. The application must set this bit only if Endpoint enable is already set for this endpoint.
- Bits 29:28 Reserved, must be kept at reset value.
- Bit 27 **SNAK**: Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.
- Bit 26 **CNAK**: Clear NAK  
**A write to this bit clears the NAK bit for the endpoint.**
- Bits 25:22 **TXFNUM**: TxFIFO number  
This value is set to the FIFO number that is assigned to IN endpoint 0.
- Bit 21 **STALL**: STALL handshake  
The application can only set this bit, and the core clears it when a SETUP token is received for this endpoint. If a NAK bit, a Global IN NAK or Global OUT NAK is set along with this bit, the STALL bit takes priority.
- Bit 20 Reserved, must be kept at reset value.
- Bits 19:18 **EPTYP**: Endpoint type  
Hardcoded to '00' for control.
- Bit 17 **NAKSTS**: NAK status  
Indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status  
1: The core is transmitting NAK handshakes on this endpoint.  
When this bit is set, either by the application or core, the core stops transmitting data, even if there are data available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.
- Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

### OTG device endpoint x control register (OTG\_FS\_DIEPCTLx) (x = 1..3, where x = Endpoint\_number)

Address offset:  $0x900 + 0x20 * x$

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

| 31    | 30 | 29    | 28 | 27      | 26 | 25              | 24 | 23   | 22 | 21   | 20 | 19     | 18 | 17 | 16 | 15    | 14 | 13       | 12 | 11    | 10 | 9      | 8  | 7          | 6  | 5      | 4  | 3        | 2 | 1 | 0 |  |  |       |  |  |  |  |  |  |  |  |  |  |  |

| EPENA |    | EPDIS |    | SODDFRM |    | SD0PID/SEVNFIRM |    | SNAK |    | CNAK |    | TXFNUM |    |    |    | STALL |    | Reserved |    | EPTYP |    | NAKSTS |    | EONUM/DPID |    | USBAEP |    | Reserved |   |   |   |  |  | MPSIZ |  |  |  |  |  |  |  |  |  |  |  |
| rs    | rs | w     | w  | w       | w  | rw              | rw | rw   | rw | rw   | rw | rw     | rw | r  | r  | rw    | rw |          |    | rw    | rw | rw     | rw | rw         | rw | rw     | rw |          |   |   |   |  |  |       |  |  |  |  |  |  |  |  |  |  |  |

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on an endpoint.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint disabled interrupt. The application must set this bit only if Endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame

Applies to isochronous IN and OUT endpoints only.

Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

- Bit 28 **SD0PID**: Set DATA0 PID  
Applies to interrupt/bulk IN endpoints only.  
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.
- SEVNFRM**: Set even frame  
Applies to isochronous IN endpoints only.  
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
- Bit 27 **SNAK**: Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a Transfer completed interrupt, or after a SETUP is received on the endpoint.
- Bit 26 **CNAK**: Clear NAK  
A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 **TXFNUM**: TxFIFO number  
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.  
This field is valid only for IN endpoints.
- Bit 21 **STALL**: STALL handshake  
Applies to non-control, non-isochronous IN endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.  
Only the application can clear this bit, never the core.
- Bit 20 Reserved, must be kept at reset value.
- Bits 19:18 **EPTYP**: Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt
- Bit 17 **NAKSTS**: NAK status  
It indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:  
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the TxFIFO.  
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the TxFIFO.  
Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame

Applies to isochronous IN endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame

1: Odd frame

**DPID**: Endpoint data PID

Applies to interrupt/bulk IN endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

0: DATA0

1: DATA1

Bit 15 **USBAEP**: USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

## OTG\_FS device control OUT endpoint 0 control register (OTG\_FS\_DOEPCTL0)

Address offset: 0xB00

Reset value: 0x0000 8000

This section describes the OTG\_FS\_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

| 31    | 30    | 29       | 28 | 27 | 26 | 25   | 24   | 23       | 22 | 21 | 20 | 19    | 18   | 17    | 16 | 15     | 14       | 13     | 12       | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2     | 1 | 0 |
|-------|-------|----------|----|----|----|------|------|----------|----|----|----|-------|------|-------|----|--------|----------|--------|----------|----|----|---|---|---|---|---|---|---|-------|---|---|
| EPENA | EPDIS | Reserved |    |    |    | SNAK | CNAK | Reserved |    |    |    | STALL | SNPM | EPTYP |    | NAKSTS | Reserved | USBAEP | Reserved |    |    |   |   |   |   |   |   |   | MPSIZ |   |   |
| w     | r     |          |    |    |    | w    | w    |          |    |    |    | rs    | rw   | r     | r  | r      |          | r      |          |    |    |   |   |   |   |   |   |   | r     | r |   |

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on endpoint 0.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application cannot disable control OUT endpoint 0.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **SNAK**: Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a Transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake

The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP**: Endpoint type

Hardcoded to 2'b00 for control.

**Bit 17 NAKSTS:** NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit, the core stops receiving data, even if there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

**Bit 15 USBAEP:** USB active endpoint

This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

**Bits 1:0 MPSIZ:** Maximum packet size

The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

### OTG\_FS device endpoint-x control register (OTG\_FS\_DOEPCTLx) (x = 1..3, where x = Endpoint\_number)

Address offset for OUT endpoints:  $0xB00 + 0x20 * x$

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

| 31    | 30    | 29             | 28             | 27   | 26   | 25       | 24 | 23 | 22 | 21 | 20    | 19   | 18    | 17     | 16         | 15     | 14       | 13 | 12 | 11 | 10 | 9     | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-------|-------|----------------|----------------|------|------|----------|----|----|----|----|-------|------|-------|--------|------------|--------|----------|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|
| EPENA | EPDIS | SODDFRM/SD1PID | SD0PID/SEVNFRM | SNAK | CNAK | Reserved |    |    |    |    | STALL | SNPM | EPTYP | NAKSTS | EONUM/DPID | USBAEP | Reserved |    |    |    |    | MPSIZ |    |    |    |    |    |    |    |    |    |
| rs    | rs    | w              | w              | w    | w    |          |    |    |    |    | rw    | rw   | rw    | rw     | r          | r      | rw       |    |    |    |    | rw    | rw | rw | rw | rw | rw | rw | rw | rw | rw |

**Bit 31 EPENA:** Endpoint enable

Applies to IN and OUT endpoints.

The application sets this bit to start transmitting data on an endpoint.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

- Bit 30 **EPDIS**: Endpoint disable  
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint disabled interrupt. The application must set this bit only if Endpoint enable is already set for this endpoint.
- Bit 29 **SD1PID**: Set DATA1 PID  
Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.  
**SODDFRM**: Set odd frame  
Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.
- Bit 28 **SD0PID**: Set DATA0 PID  
Applies to interrupt/bulk OUT endpoints only.  
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.  
**SEVNFRM**: Set even frame  
Applies to isochronous OUT endpoints only.  
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
- Bit 27 **SNACK**: Set NAK  
A write to this bit sets the NAK bit for the endpoint.  
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a Transfer Completed interrupt, or after a SETUP is received on the endpoint.
- Bit 26 **CNAK**: Clear NAK  
A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 Reserved, must be kept at reset value.
- Bit 21 **STALL**: STALL handshake  
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).  
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.
- Bit 20 **SNPM**: Snoop mode  
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.
- Bits 19:18 **EPTYP**: Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt

Bit 17 **NAKSTS**: NAK status

Indicates the following:

0: The core is transmitting non-NAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet.

Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **ONUM**: Even/odd frame

Applies to isochronous IN and OUT endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

0: Even frame

1: Odd frame

**DPID**: Endpoint data PID

Applies to interrupt/bulk OUT endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

0: DATA0

1: DATA1

Bit 15 **USBAEP**: USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### OTG\_FS device endpoint-x interrupt register (OTG\_FS\_DIEPINTx) (x = 0..3, where x = Endpoint\_number)

Address offset: 0x908 + 0x20 \* x

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 394](#). The application must read this register when the IN endpoints interrupt bit of the Core interrupt register (IEPINT in OTG\_FS\_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG\_FS\_DAINTE) register to get the exact endpoint number for the Device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_FS\_DAINTE and OTG\_FS\_GINTSTS registers.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13    | 12       | 11        | 10       | 9 | 8 | 7 | 6 | 5 | 4     | 3      | 2      | 1      | 0     |          |        |       |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----------|-----------|----------|---|---|---|---|---|-------|--------|--------|--------|-------|----------|--------|-------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | NAK   | Reserved | PKTDRPSTS | Reserved |   |   |   |   |   | TXFE  | INEPNE | INEPNM | ITTXFE | TOC   | Reserved | EPDISD | XFRC  |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rc_w1 |          |           |          |   |   |   |   |   | rc_w1 | rc_w1  | r      | rc_w1  | rc_w1 |          | rc_w1  | rc_w1 |

Bits 31:14 Reserved, must be kept at reset value.

#### Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

#### Bit 11 **PKTDRPSTS**: Packet dropped status

This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bits 10:8 Reserved, must be kept at reset value.

#### Bit 7 **TXFE**: Transmit FIFO empty

This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG\_FS\_GAHBCFG register (TXFELVL bit in OTG\_FS\_GAHBCFG).

#### Bit 6 **INEPNE**: IN endpoint NAK effective

This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG\_FS\_DIEPCTLx.

This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.

This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

#### Bit 5 **INEPNM**: IN token received with EP mismatch.

Indicates that the data in the top of the non-periodic Tx FIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

- Bit 4 **ITTXFE**: IN token received when TxFIFO is empty  
 Applies to non-periodic IN endpoints only.  
 Indicates that an IN token was received when the associated TxFIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.
- Bit 3 **TOC**: Timeout condition  
 Applies only to Control IN endpoints.  
 Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.
- Bit 2 Reserved, must be kept at reset value.
- Bit 1 **EPDISD**: Endpoint disabled interrupt  
 This bit indicates that the endpoint is disabled per the application's request.
- Bit 0 **XFRC**: Transfer completed interrupt  
 This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### OTG\_FS device endpoint-x interrupt register (OTG\_FS\_DOEPINTx) (x = 0..3, where x = Endpoint\_number)

Address offset:  $0xB08 + 0x20 * x$

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 394](#). The application must read this register when the OUT Endpoints Interrupt bit of the OTG\_FS\_GINTSTS register (OEPINT bit in OTG\_FS\_GINTSTS) is set. Before the application can read this register, it must first read the OTG\_FS\_DAIN register to get the exact endpoint number for the OTG\_FS\_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_FS\_DAIN and OTG\_FS\_GINTSTS registers.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |      |          |           |          |          |         |      |          |        |      |       |       |       |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|------|----------|-----------|----------|----------|---------|------|----------|--------|------|-------|-------|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13    | 12   | 11       | 10        | 9        | 8        | 7       | 6    | 5        | 4      | 3    | 2     | 1     | 0     |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | NAK   | BERR | Reserved | OUTPKTERR | Reserved | STSPHSRX | OTEPDIS | STUP | Reserved | EPDISD | XFRC |       |       |       |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rc_w1 |      |          | rc_w1     |          |          |         |      |          | rc_w1  |      | rc_w1 | rc_w1 | rc_w1 |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **OUTPKTERR**: OUT packet error

This interrupt is asserted when the core detects an overflow or a CRC error for an OUT packet. This interrupt is valid only when thresholding is enabled.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STSPHSRX**: Status phase received for control write

This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled

Applies only to control OUT endpoints.

Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done

Applies to control OUT endpoint only.

Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### OTG\_FS device IN endpoint 0 transfer size register (OTG\_FS\_DIEPTSIZ0)

Address offset: 0x910

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG\_FS\_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

|          |    |    |    |    |    |    |    |    |    |    |        |     |          |    |    |    |    |    |    |    |    |   |   |        |     |     |     |     |     |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|--------|-----|----------|----|----|----|----|----|----|----|----|---|---|--------|-----|-----|-----|-----|-----|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19  | 18       | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7      | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    | PKTCNT |     | Reserved |    |    |    |    |    |    |    |    |   |   | XFRSIZ |     |     |     |     |     |     |     |
|          |    |    |    |    |    |    |    |    |    |    | r/w    | r/w |          |    |    |    |    |    |    |    |    |   |   | r/w    | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:19 **PKTCNT**: Packet count

Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.

This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the TxFIFO.

**OTG\_FS device OUT endpoint 0 transfer size register (OTG\_FS\_DOEPTSIZ0)**

Address offset: 0xB10

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the Endpoint enable bit in the OTG\_FS\_DOEPCTL0 registers (EPENA bit in OTG\_FS\_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

|          |         |    |          |    |    |    |    |    |    |    |        |          |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|---------|----|----------|----|----|----|----|----|----|----|--------|----------|----|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30      | 29 | 28       | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19       | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11     | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |    |    |    |
| Reserved | STUPCNT |    | Reserved |    |    |    |    |    |    |    | PKTCNT | Reserved |    |    |    |    |    |    |    | XFRSIZ |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|          | rw      | rw |          |    |    |    |    |    |    |    | rw     |          |    |    |    |    |    |    |    | rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **STUPCNT**: SETUP packet count

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:20 Reserved, must be kept at reset value.

Bit 19 **PKTCNT**: Packet count

This field is decremented to zero after a packet is written into the RxFIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.

### OTG\_FS device endpoint-x transfer size register (OTG\_FS\_DIEPTSIZx) (x = 1..3, where x = Endpoint\_number)

Address offset:  $0x910 + 0x20 * x$

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the Endpoint enable bit in the OTG\_FS\_DIEPCTLx registers (EPENA bit in OTG\_FS\_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28:19 **PKTCNT**: Packet count

Indicates the total number of USB packets that constitute the Transfer Size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.

Bits 18:0 **XFRSIZ**: Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the TxFIFO.

### OTG\_FS device IN endpoint transmit FIFO status register (OTG\_FS\_DTXFSTSx) (x = 0..3, where x = Endpoint\_number)

Address offset for IN endpoints:  $0x918 + 0x20 * x$

This read-only register contains the free space information for the Device IN endpoint TxFIFO.

31:16 Reserved, must be kept at reset value.

15:0 **INEPTFSAV**: IN endpoint TxFIFO space available

Indicates the amount of free space available in the Endpoint TxFIFO.

Values are in terms of 32-bit words:

0x0: Endpoint TxFIFO is full

0x1: 1 word available

0x2: 2 words available

0xn: n words available

Others: Reserved

### OTG\_FS device OUT endpoint-x transfer size register (OTG\_FS\_DOEPTSIZx) (x = 1..3, where x = Endpoint\_number)

Address offset:  $0xB10 + 0x20 * x$

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the OTG\_FS\_DOEPCTLx registers (EPENA bit in OTG\_FS\_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **RXDPID**: Received data PID

Applies to isochronous OUT endpoints only.

This is the data PID received in the last packet for this endpoint.

00: DATA0

01: DATA2

10: DATA1

11: MDATA

**STUPCNT:** SETUP packet count

Applies to control OUT Endpoints only.

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bit 28:19 **PKTCNT:** Packet count

Indicates the total number of USB packets that constitute the Transfer Size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is written to the RxFIFO.

Bits 18:0 **XFRSIZ:** Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.

### 34.16.5 OTG\_FS power and clock gating control register (OTG\_FS\_PCGCCTL)

Address offset: 0xE00

Reset value: 0x0000 0000

This register is available in host and device modes.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |         |          |          |         |

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | rw      |          | rw       | rw      |

Bit 31:5 Reserved, must be kept at reset value.

Bit 4 **PHYSUSP:** PHY Suspended

Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit (bit 0).

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK:** Gate HCLK

The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK:** Stop PHY clock

The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

## 34.16.6 OTG\_FS register map

The table below gives the USB OTG register map and reset values.

Table 206. OTG\_FS register map and reset values

| Offset | Register                      | 31       | 30       | 29      | 28       | 27       | 26 | 25     | 24    | 23      | 22       | 21 | 20 | 19     | 18              | 17       | 16       | 15       | 14       | 13     | 12       | 11     | 10       | 9        | 8        | 7        | 6        | 5       | 4        | 3     | 2     | 1     | 0         |           |         |         |      |        |       |          |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 34.17 OTG\_FS programming model

### 34.17.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG\_FS\_GINTSTS (CMOD bit in OTG\_FS\_GINTSTS) reflects the mode. The OTG\_FS controller enters host mode when an "A" plug is connected or device mode when a "B" plug is connected.

This section explains the initialization of the OTG\_FS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core's configuration:

1. Program the following fields in the OTG\_FS\_GAHBCFG register:
  - Global interrupt mask bit GINTMSK = 1
  - RxFIFO non-empty (RXFLVL bit in OTG\_FS\_GINTSTS)
  - Periodic TxFIFO empty level
2. Program the following fields in the OTG\_FS\_GUSBCFG register:
  - HNP capable bit
  - SRP capable bit
  - FS timeout calibration field
  - USB turnaround time field
3. The software must unmask the following bits in the OTG\_FS\_GINTMSK register:
  - OTG interrupt mask
  - Mode mismatch interrupt mask
4. The software can read the CMOD bit in OTG\_FS\_GINTSTS to determine whether the OTG\_FS controller is operating in host or device mode.

### 34.17.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG\_FS\_GINTMSK register to unmask
2. Program the OTG\_FS\_HCFG register to select full-speed host
3. Program the PPWR bit in OTG\_FS\_HPRT to 1. This drives  $V_{BUS}$  on the USB.
4. Wait for the PCDET interrupt in OTG\_FS\_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG\_FS\_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG\_FS\_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG\_FS\_HPRT.
9. Read the PSPD bit in OTG\_FS\_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG\_FS\_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG\_FS\_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG\_FS\_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG\_FS\_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

### 34.17.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG\_FS\_DCFG register:
  - Device speed
  - Non-zero-length status OUT handshake
2. Program the OTG\_FS\_GINTMSK register to unmask the following interrupts:
  - USB reset
  - Enumeration done
  - Early suspend
  - USB suspend
  - SOF
3. Program the VBUSSEN bit in the OTG\_FS\_GCCFG register to enable  $V_{BUS}$  sensing in “B” device mode and supply the 5 volts across the pull-up resistor on the DP line.
4. Wait for the USBRST interrupt in OTG\_FS\_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.

Wait for the ENUMDNE interrupt in OTG\_FS\_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG\_FS\_DSTS

register to determine the enumeration speed and perform the steps listed in [Endpoint initialization on enumeration completion on page 1356](#).

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

### 34.17.4 Host programming model

#### Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the OTG\_FS\_GINTMSK register to unmask the following:
2. Channel interrupt
  - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
  - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG\_FS\_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG\_FS\_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG\_FS\_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the OTG\_FS\_HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

#### Halting a channel

The application can disable any channel by programming the OTG\_FS\_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG\_FS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG\_FS\_HCINTx before reallocating the channel for other transactions. The OTG\_FS host does not interrupt the transaction that has already been started on the USB.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the Request queue is full (before disabling the channel), by programming the OTG\_FS\_HCCHARx register with the CHDIS bit set to 1, and the CHENA bit cleared to 0.

The application is expected to disable a channel on any of the following conditions:

1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG\_FS\_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, Data, TXERR) for the same channel before receiving the halt.
2. When a DISCINT (Disconnect Device) interrupt in OTG\_FS\_GINTSTS is received. (The application is expected to disable all enabled channels).
3. When the application aborts a transfer before normal completion.

### Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**

The OTG\_FS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in words. If the packet size is non-word aligned, the application must use padding. The OTG\_FS host determines the actual packet size based on the programmed maximum packet size and transfer size.

**Figure 396. Transmit FIFO write task**

- **Reading the receive FIFO**

The application must ignore all packet statuses other than IN data packet (bx0010).

**Figure 397. Receive FIFO read task**

- **Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in [Figure 398](#). See channel 1 (ch\_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The non-periodic transmit FIFO can hold two packets (128 bytes for FS).
- The non-periodic request queue depth = 4.

- **Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

- Initialize channel 1
- Write the first packet for channel 1
- Along with the last word write, the core writes an entry to the non-periodic request queue
- As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
- Write the second (last) packet for channel 1
- The core generates the XFRC interrupt as soon as the last transaction is completed successfully

- g) In response to the XFRC interrupt, de-allocate the channel for other transfers
- h) Handling non-ACK responses

Figure 398. Normal bulk/control OUT/SETUP and bulk/control IN transactions

ai15675

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**

- a) Bulk/Control OUT/SETUP

```

Unmask (NAK/TXERR/STALL/XFRC)
if (XFRC)
{

```

```

    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask CHH
    Disable Channel
}
else if (NAK or TXERR )
{
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

The application is expected to write the data packets into the transmit FIFO as and when the space is available in the transmit FIFO and the Request queue. The application can make use of the NPTXFE interrupt in OTG\_FS\_GINTSTS to find the transmit FIFO space.

b) Bulk/Control IN

```

Unmask (TXERR/XFRC/BBERR/STALL/DTERR)
if (XFRC)
{
    Reset Error Count
}

```

```

    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DTERR)
{
    Reset Error Count
}

```

The application is expected to write the requests as and when the Request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**

A typical bulk or control IN pipelined transaction-level operation is shown in [Figure 399](#). See channel 2 (ch\_2). The assumptions are:

- The application is attempting to receive two maximum-packet-size packets (transfer size = 1 024 bytes).
- The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (72 bytes for FS).
- The non-periodic request queue depth = 4.

Figure 399. Bulk/control IN transactions

ai15675

The sequence of operations is as follows:

- Initialize channel 2.
- Set the CHENA bit in HCCHAR2 to write an IN request to the non-periodic request queue.
- The core attempts to send an IN token after completing the current OUT transaction.
- The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
- In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.

- f) The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
- g) The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR  $\neq$  0b0010).
- h) The core generates the XFRC interrupt as soon as the receive packet status is read.
- i) In response to the XFRC interrupt, disable the channel and stop writing the OTG\_FS\_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG\_FS\_HCCHAR2 register is written.
- j) The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
- k) Read and ignore the receive packet status.
- l) The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
- m) In response to the CHH interrupt, de-allocate the channel for other transfers.
- n) Handling non-ACK responses
- **Control transactions**  
Setup, Data, and Status stages of a control transfer must be performed as three separate transfers. Setup-, Data- or Status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or Status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in OTG\_FS\_HCCHAR1 to Control. During the Setup stage, the application is expected to set the PID field in OTG\_FS\_HCTSIZ1 to SETUP.
- **Interrupt OUT transactions**  
A typical interrupt OUT operation is shown in [Figure 400](#). The assumptions are:
  - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
  - The periodic transmit FIFO can hold one packet (1 KB)
  - Periodic request queue depth = 4
 The sequence of operations is as follows:
  - a) Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_FS\_HCCHAR1.
  - b) Write the first packet for channel 1.
  - c) Along with the last word write of each packet, the OTG\_FS host writes an entry to the periodic request queue.
  - d) The OTG\_FS host attempts to send an OUT token in the next (odd) frame.
  - e) The OTG\_FS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
  - f) In response to the XFRC interrupt, reinitialize the channel for the next transfer.

Figure 400. Normal interrupt OUT/IN transactions

ai15676

- Interrupt service routine for interrupt OUT/IN transactions

- a) Interrupt OUT

```
Unmask (NAK/TXERR/STALL/XFRC/FRMOR)
```

```
if (XFRC)
```

```
{
  Reset Error Count
  Mask ACK
  De-allocate Channel
}
```

```
else
```

```
  if (STALL or FRMOR)
```

```
  {
    Mask ACK
    Unmask CHH
  }
```

```

    Disable Channel
    if (STALL)
    {
        Transfer Done = 1
    }
}
else
    if (NAK or TXERR)
    {
        Rewind Buffer Pointers
        Reset Error Count
        Mask ACK
        Unmask CHH
        Disable Channel
    }
    else
        if (CHH)
        {
            Mask CHH
            if (Transfer Done or (Error_count == 3))
            {
                De-allocate Channel
            }
            else
            {
                Re-initialize Channel (in next b_interval - 1 Frame)
            }
        }
    else
        if (ACK)
        {
            Reset Error Count
            Mask ACK
        }

```

The application uses the NPTXFE interrupt in OTG\_FS\_GINTSTS to find the transmit FIFO space.

b) Interrupt IN

```

Unmask (NAK/TXERR/XFRC/BBERR/STALL/FRMOR/DTERR)
if (XFRC)
{
    Reset Error Count
    Mask ACK
    if (OTG_FS_HCTSIZx.PKTCNT == 0)
    {
        De-allocate Channel
    }
    else
    {
        Transfer Done = 1
        Unmask CHH
        Disable Channel
    }
}

```

```
    }
  }
else
  if (STALL or FRMOR or NAK or DTERR or BBERR)
  {
    Mask ACK
    Unmask CHH
    Disable Channel
    if (STALL or BBERR)
    {
      Reset Error Count
      Transfer Done = 1
    }
    else
      if (!FRMOR)
      {
        Reset Error Count
      }
  }
else
  if (TXERR)
  {
    Increment Error Count
    Unmask ACK
    Unmask CHH
    Disable Channel
  }
else
  if (CHH)
  {
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
      De-allocate Channel
    }
    else
      Re-initialize Channel (in next b_interval - 1 /Frame)
  }
}
else
  if (ACK)
  {
    Reset Error Count
    Mask ACK
```

}

- **Interrupt IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
- Periodic request queue depth = 4.

- **Normal interrupt IN operation**

The sequence of operations is as follows:

- a) Initialize channel 2. The application must set the ODDFRM bit in OTG\_FS\_HCCHAR2.
- b) Set the CHENA bit in OTG\_FS\_HCCHAR2 to write an IN request to the periodic request queue.
- c) The OTG\_FS host writes an IN request to the periodic request queue for each OTG\_FS\_HCCHAR2 register write with the CHENA bit set.
- d) The OTG\_FS host attempts to send an IN token in the next (odd) frame.
- e) As soon as the IN packet is received and written to the receive FIFO, the OTG\_FS host generates an RXFLVL interrupt.
- f) In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
- g) The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
- h) The core generates an XFRC interrupt as soon as the receive packet status is read.
- i) In response to the XFRC interrupt, read the PKTCNT field in OTG\_FS\_HCTSIZ2. If the PKTCNT bit in OTG\_FS\_HCTSIZ2 is not equal to 0, disable the channel before re-initializing the channel for the next transfer, if any). If PKTCNT bit in

OTG\_FS\_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_FS\_HCCHAR2.

- **Isochronous OUT transactions**

A typical isochronous OUT operation is shown in [Figure 401](#). The assumptions are:

- The application is attempting to send one packet every frame (up to 1 maximum packet size), starting with an odd frame. (transfer size = 1 024 bytes).
- The periodic transmit FIFO can hold one packet (1 KB).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

- a) Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_FS\_HCCHAR1.
- b) Write the first packet for channel 1.
- c) Along with the last word write of each packet, the OTG\_FS host writes an entry to the periodic request queue.
- d) The OTG\_FS host attempts to send the OUT token in the next frame (odd).
- e) The OTG\_FS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
- f) In response to the XFRC interrupt, reinitialize the channel for the next transfer.
- g) Handling non-ACK responses

**Figure 401. Normal isochronous OUT/IN transactions**

Re-initialize Channel
}
}
}
```

- **Isochronous IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

- Initialize channel 2. The application must set the ODDFRM bit in OTG\_FS\_HCCHAR2.
- Set the CHENA bit in OTG\_FS\_HCCHAR2 to write an IN request to the periodic request queue.
- The OTG\_FS host writes an IN request to the periodic request queue for each OTG\_FS\_HCCHAR2 register write with the CHENA bit set.
- The OTG\_FS host attempts to send an IN token in the next odd frame.
- As soon as the IN packet is received and written to the receive FIFO, the OTG\_FS host generates an RXFLVL interrupt.
- In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
- The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG\_FS\_GRXSTSR ≠ 0b0010).
- The core generates an XFRC interrupt as soon as the receive packet status is read.
- In response to the XFRC interrupt, read the PKTCNT field in OTG\_FS\_HCTSIZ2. If PKTCNT ≠ 0 in OTG\_FS\_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG\_FS\_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_FS\_HCCHAR2.

- **Selecting the queue depth**

Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

The non-periodic request queue depth affects the performance of non-periodic transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core's periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**

OTG\_FS controller handles two cases of babble: packet babble and port babble.

Packet babble occurs if the device sends more data than the maximum packet size for

the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When OTG\_FS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

When OTG\_FS controller detects a port babble, it flushes the RxFIFO and disables the port. The core then generates a Port disabled interrupt (HPRTINT in OTG\_FS\_GINTSTS, PENCHNG in OTG\_FS\_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the Port Disabled interrupt) by checking POCA in OTG\_FS\_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

### 34.17.5 Device programming model

#### Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
  - SNAK = 1 in OTG\_FS\_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
  - INEP0 = 1 in OTG\_FS\_DAINMSK (control 0 IN endpoint)
  - OUTEP0 = 1 in OTG\_FS\_DAINMSK (control 0 OUT endpoint)
  - STUP = 1 in DOEPMSK
  - XFRC = 1 in DOEPMSK
  - XFRC = 1 in DIEPMSK
  - TOC = 1 in DIEPMSK
3. Set up the Data FIFO RAM for each of the FIFOs
  - Program the OTG\_FS\_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
  - Program the OTG\_FS\_TX0FSIZ register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
  - STUPCNT = 3 in OTG\_FS\_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)

At this point, all initialization required to receive SETUP packets is done.

#### Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG\_FS\_GINTSTS), read the OTG\_FS\_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG\_FS\_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

### Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG\_FS\_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet

### Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG\_FS\_DAINMSK register.
5. Set up the Data FIFO RAM for each FIFO.
6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

### Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG\_FS\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_FS\_DOEPCTLx register (for OUT or bidirectional endpoints).
  - Maximum packet size
  - USB active endpoint = 1
  - Endpoint start data toggle (for interrupt and bulk endpoints)
  - Endpoint type
  - TxFIFO number
2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

## Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG\_FS\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_FS\_DOEPCTLx register (for OUT or bidirectional endpoints).
2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

*Note:* The application must meet the following conditions to set up the device core to handle traffic:  
NPTXFEM and RXFLVLM in the OTG\_FS\_GINTMSK register must be cleared.

## 34.17.6 Operational model

### SETUP and OUT data transfers

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

#### • Packet read

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

1. On catching an RXFLVL interrupt (OTG\_FS\_GINTSTS register), the application must read the Receive status pop register (OTG\_FS\_GRXSTSP).
2. The application can mask the RXFLVL interrupt (in OTG\_FS\_GINTSTS) by writing to RXFLVL = 0 (in OTG\_FS\_GINTMSK), until it has read the packet from the receive FIFO.
3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive Data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.
4. The receive FIFO's packet status readout indicates one of the following:
  - a) Global OUT NAK pattern:  
PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = Don't Care (0x0), DPID = Don't Care (0b00).  
These data indicate that the global OUT NAK bit has taken effect.
  - b) SETUP packet pattern:  
PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num, DPID = D0.  
These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
  - c) Setup stage done pattern:  
PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = Don't Care (0b00).  
These data indicate that the Setup stage for the specified endpoint has completed and the Data stage has started. After this entry is popped from the receive FIFO, the core asserts a Setup interrupt on the specified control OUT endpoint.
  - d) Data OUT packet pattern:  
PKTSTS = DataOUT, BCNT = size of the received data OUT packet ( $0 \leq \text{BCNT} \leq 1\,024$ ), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.

- e) Data transfer completed pattern:  
 PKTSTS = Data OUT Transfer Done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = Don't Care (0b00).  
 These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a Transfer Completed interrupt on the specified OUT endpoint.
5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG\_FS\_GINTSTS) must be unmasked.
6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG\_FS\_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

Figure 402 provides a flowchart of the above procedure.

**Figure 402. Receive FIFO packet read**

#### • SETUP transactions

This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

#### • Application requirements

1. To receive a SETUP packet, the STUPCNT field (OTG\_FS\_DOEPTSLZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG\_FS\_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to

determine the correct number of SETUP packets received in the Setup stage of a control transfer.

- STUPCNT = 3 in OTG\_FS\_DOEPTSIZEx
- 2. The application must always allocate some extra space in the Receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
  - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the Setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
  - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (Setup packet pattern). The core reserves this space in the receive data FIFO to write SETUP data only, and never uses this space for data packets.
- 3. The application must read the 2 words of the SETUP packet from the receive FIFO.
- 4. The application must read and discard the Setup stage done word from the receive FIFO.

- **Internal data flow**

1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
  - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
  - The first word contains control information used internally by the core
  - The second word contains the first 4 bytes of the SETUP command
  - The third word contains the last 4 bytes of the SETUP command
3. When the Setup stage changes to a Data IN/OUT stage, the core writes an entry (Setup stage done word) to the receive FIFO, indicating the completion of the Setup stage.
4. On the AHB side, SETUP packets are emptied by the application.
5. When the application pops the Setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG\_FS\_DOEPINTx), indicating it can process the received SETUP packet.
  - The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**

1. Program the OTG\_FS\_DOEPTSIZEx register.
  - STUPCNT = 3
2. Wait for the RXFLVL interrupt (OTG\_FS\_GINTSTS) and empty the data packets from the receive FIFO.
3. Assertion of the STUP interrupt (OTG\_FS\_DOEPINTx) marks a successful completion of the SETUP Data Transfer.
  - On this interrupt, the application must read the OTG\_FS\_DOEPTSIZEx register to determine the number of SETUP packets received and process the last received SETUP packet.

**Figure 403. Processing a SETUP packet**

- **Handling more than three back-to-back SETUP packets**

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG\_FS controller generates an interrupt (B2BSTUP in OTG\_FS\_DOEPINTx).

- **Setting the global OUT NAK**

**Internal data flow**

1. When the application sets the Global OUT NAK (SGONAK bit in OTG\_FS\_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG\_FS\_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG\_FS\_DCTL.

**Application programming sequence**

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
  - SGONAK = 1 in OTG\_FS\_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG\_FS\_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG\_FS\_DCTL and before the core asserts the GONAKEFF interrupt (OTG\_FS\_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GINAKEFFM bit in the OTG\_FS\_GINTMSK register.
  - GINAKEFFM = 0 in the OTG\_FS\_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG\_FS\_DCTL. This also clears the GONAKEFF interrupt (OTG\_FS\_GINTSTS).
  - OTG\_FS\_DCTL = 1 in CGONAK
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
  - GINAKEFFM = 1 in GINTMSK

- **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

**Application programming sequence**

1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
  - SGONAK = 1 in OTG\_FS\_DCTL
2. Wait for the GONAKEFF interrupt (OTG\_FS\_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
  - EPDIS = 1 in OTG\_FS\_DOEPCTLx
  - SNAK = 1 in OTG\_FS\_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG\_FS\_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
  - EPDIS = 0 in OTG\_FS\_DOEPCTLx
  - EPENA = 0 in OTG\_FS\_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
  - SGONAK = 0 in OTG\_FS\_DCTL

- **Transfer Stop Programming for OUT endpoints**

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

**Sequence of operations:**

1. Enable all OUT endpoints by setting
  - EPENA = 1 in all OTG\_FS\_DOEPCTLx registers.
2. Flush the Rx FIFO as follows
  - Poll OTG\_FS\_GRSTCTL.AHBIDL until it is 1. This indicates that AHB master is idle.
  - Perform read modify write operation on OTG\_FS\_GRSTCTL.RXFFLSH = 1
  - Poll OTG\_FS\_GRSTCTL.RXFFLSH until it is 0, but also using a timeout of less than 10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen before the timeout, then the Rx FIFO flush is successful. If at the moment the timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from the host) then go back (once only) to the previous step (“Perform read modify write operation”).
3. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in “[Setting the global OUT NAK on page 1361](#)”. This ensures that data in the Rx FIFO is sent to the application successfully. Set SGONAK = 1 in OTG\_FS\_DCTL
4. Wait for the GONAKEFF interrupt (OTG\_FS\_GINTSTS)
5. Disable all active OUT endpoints by programming the following register bits:
  - EPDIS = 1 in registers OTG\_FS\_DOEPCTLx
  - SNAK = 1 in registers OTG\_FS\_DOEPCTLx
6. Wait for the EPDIS interrupt in OTG\_FS\_DOEPINTx for each OUT endpoint programmed in the previous step. The EPDIS interrupt in OTG\_FS\_DOEPINTx indicates that the corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is asserted, the following bits are cleared:
  - EPENA = 0 in registers OTG\_FS\_DOEPCTLx
  - EPDIS = 0 in registers OTG\_FS\_DOEPCTLx
  - SNAK = 0 in registers OTG\_FS\_DOEPCTLx

- **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

**Application requirements**

1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
  - $\text{transfer size}[\text{EPNUM}] = n \times (\text{MPSIZ}[\text{EPNUM}] + 4 - (\text{MPSIZ}[\text{EPNUM}] \bmod 4))$
  - $\text{packet count}[\text{EPNUM}] = n$
  - $n > 0$
3. On any OUT endpoint interrupt, the application must read the endpoint’s transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
  - $\text{Payload size in memory} = \text{application programmed initial transfer size} - \text{core updated final transfer size}$

- Number of USB packets in which this payload was received = application programmed initial packet count – core updated final packet count

**Internal data flow**

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
  - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
  - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
  - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
  - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
  - The transfer size is 0 and the packet count is 0
  - The last OUT data packet written to the receive FIFO is a short packet ( $0 \leq \text{packet size} < \text{maximum packet size}$ )
7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

**Application programming sequence**

1. Program the OTG\_FS\_DOEPTSIZE register for the transfer size and the corresponding packet count.
2. Program the OTG\_FS\_DOEPCTL register with the endpoint characteristics, and set the EPENA and CNAK bits.
  - EPENA = 1 in OTG\_FS\_DOEPCTL
  - CNAK = 1 in OTG\_FS\_DOEPCTL
3. Wait for the RXFLVL interrupt (in OTG\_FS\_GINTSTS) and empty the data packets from the receive FIFO.
  - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG\_FS\_DOEPINT) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG\_FS\_DOEPTSIZE register to determine the size of the received data payload.

**• Generic isochronous OUT data transfer**

This section describes a regular isochronous OUT data transfer.

**Application requirements**

1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG\_FS\_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG\_FS\_GINTSTS) and before the SOF (OTG\_FS\_GINTSTS).

**Internal data flow**

1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
  - EONUM (in OTG\_FS\_DOEPCTL) = SOFFN[0] (in OTG\_FS\_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG\_FS\_DOEPTSIZE with the data PID of the last isochronous OUT data packet read from the receive FIFO.

**Application programming sequence**

1. Program the OTG\_FS\_DOEPTISIZx register for the transfer size and the corresponding packet count
2. Program the OTG\_FS\_DOEPCTLx register with the endpoint characteristics and set the Endpoint Enable, ClearNAK, and Even/Odd frame bits.
  - EPENA = 1
  - CNAK = 1
  - EONUM = (0: Even/1: Odd)
3. Wait for the RXFLVL interrupt (in OTG\_FS\_GINTSTS) and empty the data packets from the receive FIFO
  - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG\_FS\_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the IISOXFRM interrupt in OTG\_FS\_GINTSTS.
6. Read the OTG\_FS\_DOEPTISIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
  - RXDPID = D0 (in OTG\_FS\_DOEPTISIZx) and the number of USB packets in which this payload was received = 1
  - RXDPID = D1 (in OTG\_FS\_DOEPTISIZx) and the number of USB packets in which this payload was received = 2
  - RXDPID = D2 (in OTG\_FS\_DOEPTISIZx) and the number of USB packets in which this payload was received = 3

The number of USB packets in which this payload was received =  
Application programmed initial packet count – Core updated final packet count

The application can discard invalid data packets.

- **Incomplete isochronous OUT data transfers**

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

**Internal data flow**

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG\_FS\_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application could fail to detect the XFRC interrupt (OTG\_FS\_DOEPINTx) under the following circumstances:
  - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
  - When the isochronous OUT data packet is received with CRC errors
  - When the isochronous OUT token received by the core is corrupted
  - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete Isochronous OUT data interrupt (IISOXFRM in OTG\_FS\_GINTSTS), indicating that an XFRC interrupt (in OTG\_FS\_DOEPINTx) is not asserted on at least one of the isochronous OUT

endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

#### Application programming sequence

1. Asserting the IISOXFRM interrupt (OTG\_FS\_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
  - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG\_FS\_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.
3. When it receives an IISOXFRM interrupt (in OTG\_FS\_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG\_FS\_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
  - EONUM bit (in OTG\_FS\_DOEPCTLx) = SOFFN[0] (in OTG\_FS\_DSTS)
  - EPENA = 1 (in OTG\_FS\_DOEPCTLx)
4. The previous step must be performed before the SOF interrupt (in OTG\_FS\_GINTSTS) is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG\_FS\_DOEPCTLx.
6. Wait for the EPDIS interrupt (in OTG\_FS\_DOEPINTx) and enable the endpoint to receive new data in the next frame.
  - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

#### • Stalling a non-isochronous OUT endpoint

This section describes how the application can stall a non-isochronous endpoint.

1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
  - When disabling the endpoint, instead of setting the SNAK bit in OTG\_FS\_DOEPCTL, set STALL = 1 (in OTG\_FS\_DOEPCTL).  
The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG\_FS\_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

#### Examples

This section describes and depicts some fundamental transfer types and scenarios.

- Bulk OUT transaction

Figure 404 depicts the reception of a single Bulk OUT Data packet from the USB to the AHB and describes the events involved in the process.

Figure 404. Bulk OUT transaction

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG\_FS\_DOEPCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG\_FS\_DOEPSIZx register.

1. host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG\_FS\_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG\_FS\_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG\_FS\_DOEPINTx) to determine that the intended transfer is complete.

## IN data transfers

### • Packet write

This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.

1. The application can either choose the polling or the interrupt mode.

- In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG\_FS\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - In interrupt mode, the application waits for the TXFE interrupt (in OTG\_FS\_DIEPINTx) and then reads the OTG\_FS\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
  - To write zero length packet, the application must not look at the FIFO space.
2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG\_FS\_DIEPCTLx register to avoid modifying the contents of the register, except for setting the Endpoint Enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

#### • **Setting IN endpoint NAK**

##### **Internal data flow**

1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint's transmit FIFO.
2. Non-isochronous IN tokens receive a NAK handshake reply
  - Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG\_FS\_DIEPINTx in response to the SNAK bit in OTG\_FS\_DIEPCTLx.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG\_FS\_DIEPCTLx.

##### **Application programming sequence**

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
  - SNAK = 1 in OTG\_FS\_DIEPCTLx
2. Wait for assertion of the INEPNE interrupt in OTG\_FS\_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in DIEPMSK.
  - INEPNEM = 0 in DIEPMSK
5. To exit Endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG\_FS\_DIEPCTLx. This also clears the INEPNE interrupt (in OTG\_FS\_DIEPINTx).
  - CNAK = 1 in OTG\_FS\_DIEPCTLx
6. If the application masked this interrupt earlier, it must be unmasked as follows:

- INEPNEM = 1 in DIEPMSK

- **IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

**Application programming sequence**

1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
  - SNAK = 1 in OTG\_FS\_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG\_FS\_DIEPINTx.
4. Set the following bits in the OTG\_FS\_DIEPCTLx register for the endpoint that must be disabled.
  - EPDIS = 1 in OTG\_FS\_DIEPCTLx
  - SNAK = 1 in OTG\_FS\_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG\_FS\_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
  - EPENA = 0 in OTG\_FS\_DIEPCTLx
  - EPDIS = 0 in OTG\_FS\_DIEPCTLx
6. The application must read the OTG\_FS\_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the Endpoint transmit FIFO, by setting the following fields in the OTG\_FS\_GRSTCTL register:
  - TXFNUM (in OTG\_FS\_GRSTCTL) = Endpoint transmit FIFO number
  - TXFFLSH in (OTG\_FS\_GRSTCTL) = 1

The application must poll the OTG\_FS\_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

- **Transfer Stop Programming for IN endpoints**

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

**Sequence of operations:**

1. Disable the IN endpoint by setting:
  - EPDIS = 1 in all OTG\_FS\_DIEPCTLx registers
2. Wait for the EPDIS interrupt in OTG\_FS\_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
  - EPDIS = 0 in OTG\_FS\_DIEPCTLx
  - EPENA = 0 in OTG\_FS\_DIEPCTLx
3. Flush the Tx FIFO by programming the following bits:
  - TXFFLSH = 1 in OTG\_FS\_GRSTCTL
  - TXFNUM = "FIFO number specific to endpoint" in OTG\_FS\_GRSTCTL
4. The application can start polling till TXFFLSH in OTG\_FS\_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

- **Generic non-periodic IN data transfers**

**Application requirements**

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
  - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 
$$\text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$$
 If (sp > 0), then packet count[EPNUM] = x + 1.  
 Otherwise, packet count[EPNUM] = x
  - To transmit a single zero-length data packet:
 
$$\text{Transfer size}[\text{EPNUM}] = 0$$

$$\text{Packet count}[\text{EPNUM}] = 1$$
  - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
 
$$\text{First transfer: transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{epnum}]; \text{ packet count} = n;$$

$$\text{Second transfer: transfer size}[\text{EPNUM}] = 0; \text{ packet count} = 1;$$
3. Once an endpoint is enabled for data transfers, the core updates the Transfer size register. At the end of the IN transfer, the application must read the Transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.
4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
  - Data transmitted on USB = (application-programmed initial packet count – Core updated final packet count) × MPSIZ[EPNUM]
  - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

**Internal data flow**

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when TxFIFO is empty” (ITTXFE) Interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

**Application programming sequence**

1. Program the OTG\_FS\_DIEPTSIZx register with the transfer size and corresponding packet count.
2. Program the OTG\_FS\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (Endpoint Enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG\_FS\_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG\_FS\_DIEPINTx) before writing the data.

- **Generic periodic IN data transfers**

This section describes a typical periodic IN data transfer.

**Application requirements**

1. Application requirements 1, 2, 3, and 4 of [Generic non-periodic IN data transfers](#) also apply to periodic IN data transfers, except for a slight modification of requirement 2.
  - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:
 
$$\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$$
 (where x is an integer  $\geq 0$ , and  $0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]$ )
 
$$\text{If } (\text{sp} > 0), \text{ packet count}[\text{EPNUM}] = x + 1$$
 Otherwise,  $\text{packet count}[\text{EPNUM}] = x$ ;

- MCNT[EPNUM] = packet count[EPNUM]
- The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:
    - transfer size[EPNUM] = 0
    - packet count[EPNUM] = 1
    - MCNT[EPNUM] = packet count[EPNUM]
2. The application can only schedule data transfers one frame at a time.
    - $(MCNT - 1) \times MPSIZ \leq XFERSIZ \leq MCNT \times MPSIZ$
    - PKTCNT = MCNT (in OTG\_FS\_DIEPTISZx)
    - If  $XFERSIZ < MCNT \times MPSIZ$ , the last data packet of the transfer is a short packet.
    - Note that: MCNT is in OTG\_FS\_DIEPTISZx, MPSIZ is in OTG\_FS\_DIEPCTLx, PKTCNT is in OTG\_FS\_DIEPTISZx and XFERSIZ is in OTG\_FS\_DIEPTISZx
  3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:
    - A zero data length packet would be transmitted on the USB for isochronous IN endpoints
    - A NAK handshake would be transmitted on the USB for interrupt IN endpoints

#### Internal data flow

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the associated transmit FIFO for the endpoint.
3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO mode) for the frame is not present in the FIFO, then the core generates an IN token received when TxFIFO empty interrupt for the endpoint.
  - A zero-length data packet is transmitted on the USB for isochronous IN endpoints
  - A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. The packet count for the endpoint is decremented by 1 under the following conditions:
  - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
  - For interrupt endpoints, when an ACK handshake is transmitted
  - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.
6. At the “Periodic frame Interval” (controlled by PFIVL in OTG\_FS\_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG\_FS\_GINTSTS.

**Application programming sequence**

1. Program the OTG\_FS\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG\_FS\_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG\_FS\_DIEPINTx) with no ITTXFE interrupt in OTG\_FS\_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG\_FS\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG\_FS\_DIEPINTx), with or without the ITTXFE interrupt (in OTG\_FS\_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG\_FS\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG\_FS\_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- **Incomplete isochronous IN data transfers**

This section describes what the application must do on an incomplete isochronous IN data transfer.

**Internal data flow**

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
  - a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_FS\_GINTSTS).
  - b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when TxFIFO empty interrupt in OTG\_FS\_DIEPINTx. The application can ignore this interrupt, as it eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_FS\_GINTSTS) at the end of periodic frame.  
The core transmits a zero-length data packet on the USB in response to the received IN token.
2. The application must stop writing the data payload to the transmit FIFO as soon as possible.
3. The application must set the NAK bit and the disable bit for the endpoint.
4. The core disables the endpoint, clears the disable bit, and asserts the Endpoint Disable interrupt for the endpoint.

**Application programming sequence**

1. The application can ignore the IN token received when TxFIFO empty interrupt in OTG\_FS\_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG\_FS\_GINTSTS).

2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG\_FS\_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
3. The application must read the Endpoint Control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
5. Program the following fields in the OTG\_FS\_DIEPCTLx register to disable the endpoint:
  - SNAK = 1 in OTG\_FS\_DIEPCTLx
  - EPDIS = 1 in OTG\_FS\_DIEPCTLx
6. The assertion of the Endpoint Disabled interrupt in OTG\_FS\_DIEPINTx indicates that the core has disabled the endpoint.
  - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG\_FS\_GRSTCTL register.

- **Stalling non-isochronous IN endpoints**

This section describes how the application can stall a non-isochronous endpoint.

**Application programming sequence**

1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG\_FS\_DIEPCTLx, when the endpoint is already enabled
  - STALL = 1 in OTG\_FS\_DIEPCTLx
  - The STALL bit always takes precedence over the NAK bit
3. Assertion of the Endpoint Disabled interrupt (in OTG\_FS\_DIEPINTx) indicates to the application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the STALL bit must be cleared in OTG\_FS\_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

**Special case: stalling the control OUT endpoint**

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable the ITTXFE interrupt in OTG\_FS\_DIEPINTx and the OTEPDIS interrupt in OTG\_FS\_DOEPINTx during the data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

### 34.17.7 Worst case response time

When the OTG\_FS controller acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token could come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were dropped.

#### Choosing the value of TRDT in OTG\_FS\_GUSBCFG

The value in TRDT (OTG\_FS\_GUSBCFG) is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from the PFC block. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks.

Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG\_FS\_GUSBCFG).

[Figure 405](#) has the following signals:

- `tkn_rcvd`: Token received information from MAC to PFC
- `dynced_tkn_rcvd`: Doubled sync `tkn_rcvd`, from PCLK to HCLK domain
- `spr_read`: Read to SPRAM
- `spr_addr`: Address to SPRAM
- `spr_rdata`: Read data from SPRAM
- `srcbuf_push`: Push to the source buffer
- `srcbuf_rdata`: Read data from the source buffer. Data seen by MAC

Refer to [Table 204: TRDT values](#) for the values of TRDT versus AHB clock frequency.

Figure 405. TRDT max timing case

### 34.17.8 OTG programming model

The OTG\_FS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG\_FS controller turns off  $V_{BUS}$  to conserve power. SRP is a method by which the B-device signals the A-device to turn on  $V_{BUS}$  power. A device must perform both data-line pulsing and  $V_{BUS}$  pulsing, but a host can detect either data-line pulsing or  $V_{BUS}$  pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

### A-device session request protocol

The application must set the SRP-capable bit in the Core USB configuration register. This enables the OTG\_FS controller to detect SRP as an A-device.

**Figure 406. A-device SRP**

1. DRV\_VBUS = V<sub>BUS</sub> drive signal to the PHY  
VBUS\_VALID = V<sub>BUS</sub> valid signal from PHY  
A\_VALID = A-peripheral V<sub>BUS</sub> level signal to PHY  
D+ = Data plus line  
D- = Data minus line
1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS\_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when V<sub>BUS</sub> power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG\_FS controller detects data-line pulsing.
5. The device drives V<sub>BUS</sub> above the A-device session valid (2.0 V minimum) for V<sub>BUS</sub> pulsing.  
The OTG\_FS controller interrupts the application on detecting SRP. The Session request detected bit is set in Global interrupt status register (SRQINT set in OTG\_FS\_GINTSTS).
6. The application must service the Session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS\_VALID signal.
7. When the USB is powered, the device connects, completing the SRP process.

## B-device session request protocol

The application must set the SRP-capable bit in the Core USB configuration register. This enables the OTG\_FS controller to initiate SRP as a B-device. SRP is a means by which the OTG\_FS controller can request a new session from the host.

**Figure 407. B-device SRP**

1.  $\text{VBUS\_VALID}$  =  $V_{\text{BUS}}$  valid signal from PHY  
 $\text{B\_VALID}$  = B-peripheral valid session to PHY  
 $\text{DISCHRG\_VBUS}$  = discharge signal to PHY  
 $\text{SESS\_END}$  = session end signal to PHY  
 $\text{CHRG\_VBUS}$  = charge  $V_{\text{BUS}}$  signal to PHY  
 $\text{DP}$  = Data plus line  
 $\text{DM}$  = Data minus line

1. To save power, the host suspends and turns off port power when the bus is idle.  
 The OTG\_FS controller sets the early suspend bit in the Core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS controller sets the USB suspend bit in the Core interrupt register.  
 The OTG\_FS controller informs the PHY to discharge  $V_{\text{BUS}}$ .
2. The PHY indicates the session's end to the device. This is the initial condition for SRP.  
 The OTG\_FS controller requires 2 ms of SE0 before initiating SRP.  
 For a USB 1.1 full-speed serial transceiver, the application must wait until  $V_{\text{BUS}}$  discharges to 0.2 V after BSVLD (in OTG\_FS\_GOTGCTL) is deasserted. This discharge time can be obtained from the transceiver vendor and varies from one transceiver to another.
3. The USB OTG core informs the PHY to speed up  $V_{\text{BUS}}$  discharge.
4. The application initiates SRP by writing the session request bit in the OTG Control and status register. The OTG\_FS controller perform data-line pulsing followed by  $V_{\text{BUS}}$  pulsing.
5. The host detects SRP from either the data-line or  $V_{\text{BUS}}$  pulsing, and turns on  $V_{\text{BUS}}$ .  
 The PHY indicates  $V_{\text{BUS}}$  power-on to the device.

6. The OTG\_FS controller performs  $V_{BUS}$  pulsing.  
The host starts a new session by turning on  $V_{BUS}$ , indicating SRP success. The OTG\_FS controller interrupts the application by setting the session request success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.
7. When the USB is powered, the OTG\_FS controller connects, completing the SRP process.

### A-device host negotiation protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the Core USB configuration register to enable the OTG\_FS controller to perform HNP as an A-device.

**Figure 408. A-device HNP**

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.
1. The OTG\_FS controller sends the B-device a SetFeature b\_hnp\_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP Enable bit in the OTG Control

and status register to indicate to the OTG\_FS controller that the B-device supports HNP.

2. When it has finished using the bus, the application suspends by writing the Port suspend bit in the host port control and status register.
3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The OTG\_FS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.

The OTG\_FS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG\_FS\_DP pull-up resistor to indicate a connect for B-device.

The application must read the current mode bit in the OTG Control and status register to determine device mode operation.

4. The B-device detects the connection, issues a USB reset, and enumerates the OTG\_FS controller for data traffic.
5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The OTG\_FS controller sets the early suspend bit in the Core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS controller sets the USB Suspend bit in the Core interrupt register.

6. In Negotiated mode, the OTG\_FS controller detects the suspend, disconnects, and switches back to the host role. The OTG\_FS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.
7. The OTG\_FS controller sets the Connector ID status change interrupt in the OTG Interrupt Status register. The application must read the connector ID status in the OTG Control and Status register to determine the OTG\_FS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.
8. The B-device connects, completing the HNP process.

## B-device host negotiation protocol

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the Core USB configuration register to enable the OTG\_FS controller to perform HNP as a B-device.

**Figure 409. B-device HNP**

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.
1. The A-device sends the SetFeature b\_hnp\_enable descriptor to enable HNP support. The OTG\_FS controller's ACK response indicates that it supports HNP. The application must set the device HNP enable bit in the OTG Control and status register to indicate HNP support.  
The application sets the HNP request bit in the OTG Control and status register to indicate to the OTG\_FS controller to initiate HNP.
2. When it has finished using the bus, the A-device suspends by writing the Port suspend bit in the host port control and status register.  
The OTG\_FS controller sets the Early suspend bit in the Core interrupt register after 3 ms of bus idleness. Following this, the OTG\_FS controller sets the USB suspend bit in the Core interrupt register.  
The OTG\_FS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG\_FS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.  
The A-device responds by activating its OTG\_FS\_DP pull-up resistor within 3 ms of detecting SE0. The OTG\_FS controller detects this as a connect.  
The OTG\_FS controller sets the host negotiation success status change interrupt in the OTG Interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG Control and status register to determine host negotiation success. The application must read the current Mode bit in the Core interrupt register (OTG\_FS\_GINTSTS) to determine host mode operation.
3. The application sets the reset bit (PRST in OTG\_FS\_HPRT) and the OTG\_FS controller issues a USB reset and enumerates the A-device for data traffic.

4. The OTG\_FS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the Port suspend bit in the host port control and status register.
5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG\_FS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.
6. The application must read the current mode bit in the Core interrupt (OTG\_FS\_GINTSTS) register to determine the host mode operation.
7. The OTG\_FS controller connects, completing the HNP process.

## 35 USB on-the-go high-speed (OTG\_HS)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 35.1 OTG\_HS introduction

Portions Copyright (c) 2004, 2005 Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG\_HS controller.

The following acronyms are used throughout the section:

|      |                                     |
|------|-------------------------------------|
| FS   | full-speed                          |
| HS   | High-speed                          |
| LS   | Low-speed                           |
| USB  | Universal serial bus                |
| OTG  | On-the-go                           |
| PHY  | Physical layer                      |
| MAC  | Media access controller             |
| PFC  | Packet FIFO controller              |
| UTMI | USB Transceiver Macrocell Interface |
| ULPI | UTMI+ Low Pin Interface             |

References are made to the following documents:

- USB On-The-Go Supplement, Revision 1.3
- Universal Serial Bus Revision 2.0 Specification

The OTG\_HS is a dual-role device (DRD) controller that supports both peripheral and host functions and is fully compliant with the *On-The-Go Supplement to the USB 2.0 Specification*. It can also be configured as a host-only or peripheral-only controller, fully compliant with the *USB 2.0 Specification*. In host mode, the OTG\_HS supports high-speed (HS, 480 Mbits/s), full-speed (FS, 12 Mbits/s) and low-speed (LS, 1.5 Mbits/s) transfers whereas in peripheral mode, it only supports high-speed (HS, 480Mbits/s) and full-speed (FS, 12 Mbits/s) transfers. The OTG\_HS supports both HNP and SRP. The only external device required is a charge pump for VBUS in OTG mode.

### 35.2 OTG\_HS main features

The main features can be divided into three categories: general, host-mode and peripheral-mode features.

### 35.2.1 General features

The OTG\_HS interface main features are the following:

- It is USB-IF certified in compliance with the Universal Serial Bus Revision 2.0 Specification
- It supports 3 PHY interfaces
  - An on-chip full-speed PHY
  - An ULPI interface for external high-speed PHY.
- It supports the host negotiation protocol (HNP) and the session request protocol (SRP)
- It allows the host to turn  $V_{BUS}$  off to save power in OTG applications, with no need for external components
- It allows to monitor  $V_{BUS}$  levels using internal comparators
- It supports dynamic host-peripheral role switching
- It is software-configurable to operate as:
  - An SRP-capable USB HS/FS peripheral (B-device)
  - An SRP-capable USB HS/FS/low-speed host (A-device)
  - An USB OTG FS dual-role device
- It supports HS/FS SOFs as well as low-speed (LS) keep-alive tokens with:
  - SOF pulse PAD output capability
  - SOF pulse internal connection to timer 2 (TIM2)
  - Configurable framing period
  - Configurable end-of-frame interrupt
- It embeds an internal DMA with shareholding support and software selectable AHB burst type in DMA mode
- It has power saving features such as system clock stop during USB suspend, switching off of the digital core internal clock domains, PHY and DFIFO power management
- It features a dedicated 4-Kbyte data RAM with advanced FIFO management:
  - The memory partition can be configured into different FIFOs to allow flexible and efficient use of RAM
  - Each FIFO can contain multiple packets
  - Memory allocation is performed dynamically
  - The FIFO size can be configured to values that are not powers of 2 to allow the use of contiguous memory locations
- It ensures a maximum USB bandwidth of up to one frame without application intervention

### 35.2.2 Host-mode features

The OTG\_HS interface features in host mode are the following:

- It requires an external charge pump to generate  $V_{BUS}$
- It has up to 12 host channels (pipes), each channel being dynamically reconfigurable to support any kind of USB transfer
- It features a built-in hardware scheduler holding:
  - Up to 8 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 8 control plus bulk transfer requests in the nonperiodic hardware queue
- It manages a shared RX FIFO, a periodic TX FIFO, and a nonperiodic TX FIFO for efficient usage of the USB data RAM
- It features dynamic trimming capability of SOF framing period in host mode.

### 35.2.3 Peripheral-mode features

The OTG\_HS interface main features in peripheral mode are the following:

- It has 1 bidirectional control endpoint 0
- It has 5 IN endpoints (EP) configurable to support bulk, interrupt or isochronous transfers
- It has 5 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- It manages a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- It manages up to 6 dedicated Tx-IN FIFOs (one for each IN-configured EP) to reduce the application load
- It features soft disconnect capability

## 35.3 OTG\_HS functional description

*Figure 410* shows the OTG\_HS interface block diagram.

Figure 410. USB OTG interface block diagram

1. The USB DMA cannot directly address the internal Flash memory.

### 35.3.1 OTG pins

Table 207. OTG\_HS input/output pins

| Signal name         | Signal type          | Description                                |
|---------------------|----------------------|--------------------------------------------|
| OTG_HS_DP           | Digital input/output | USB OTG D+ line                            |
| OTG_HS_DM           | Digital input/output | USB OTG D- line                            |
| OTG_HS_ID           | Digital input        | USB OTG ID                                 |
| OTG_HS_VBUS         | Analog input         | USB OTG VBUS                               |
| OTG_HS_SOF          | Digital output       | USB OTG Start Of Frame (visibility)        |
| OTG_HS_ULPI_CK      | Digital input        | USB OTG ULPI clock                         |
| OTG_HS_ULPI_DIR     | Digital input        | USB OTG ULPI data bus direction control    |
| OTG_HS_ULPI_STP     | Digital output       | USB OTG ULPI data stream stop              |
| OTG_HS_ULPI_NXT     | Digital input        | USB OTG ULPI next data stream request      |
| OTG_HS_ULPI_D[0..7] | Digital input/output | USB OTG ULPI 8-bit bi-directional data bus |

### 35.3.2 High-speed OTG PHY

The USB OTG HS core embeds an ULPI interface to connect an external HS phy.

### 35.3.3 Embedded Full-speed OTG PHY

The full-speed OTG PHY includes the following components:

- FS/LS transceiver module used by both host and Device. It directly drives transmission and reception on the single-ended USB lines.
- Integrated ID pull-up resistor used to sample the ID line for A/B Device identification.
- DP/DM integrated pull-up and pull-down resistors controlled by the OTG\_HS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as  $V_{BUS}$  is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the peripheral role is changed via the host negotiation protocol (HNP).
- Pull-up/pull-down resistor ECN circuit  
The DP pull-up consists of 2 resistors controlled separately from the OTG\_HS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows to achieve a better noise rejection and Tx/Rx signal quality.
- $V_{BUS}$  sensing comparators with hysteresis used to detect  $V_{BUS\_VALID}$ , A-B Session Valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the  $V_{BUS}$  supply during USB operations.
- $V_{BUS}$  pulsing method circuit used to charge/discharge  $V_{BUS}$  through resistors during the SRP (weak drive).

**Caution:** To guarantee a correct operation for the USB OTG HS peripheral, the AHB frequency should be higher than 30 MHz.

## 35.4 OTG dual-role device

### 35.4.1 ID line detection

The host or peripheral (the default) role depends on the level of the ID input line. It is determined when the USB cable is plugged in and depends on which side of the USB cable is connected to the micro-AB receptacle:

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG\_HS conforms to the FSM standard described in section 6.8.2: On-The-Go B-device of the USB On-The-Go Supplement, Revision 1.3.
- If the A-side of the USB cable is connected with a grounded ID, the OTG\_HS issues an ID line status change interrupt (CIDSCHG bit in the OTG\_HS\_GINTSTS register) for host software initialization, and automatically switches to host role. In this configuration the OTG\_HS conforms to the FSM standard described by section 6.8.1: On-The-Go A-Device of the USB On-The-Go Supplement, Revision 1.3.

### 35.4.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in the OTG\_HS\_GUSBCFG register) configures the OTG\_HS core to dynamically change from A-host to A-device role and vice-versa, or from B-device to B-host role and vice-versa, according to the host negotiation protocol (HNP). The current device status is defined by the

combination of the Connector ID Status bit in the Global OTG control and status register (CIDSTS bit in OTG\_HS\_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG\_HS\_GINTSTS).

The HNP programming model is described in detail in [Section 35.13: OTG\\_HS programming model](#).

### 35.4.3 SRP dual-role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_HS\_GUSBCFG) configures the OTG\_HS core to switch  $V_{BUS}$  off for the A-device in order to save power. The A-device is always in charge of driving  $V_{BUS}$  regardless of the OTG\_HS role (host or peripheral). The SRP A/B-device program model is described in detail in [Section 35.13: OTG\\_HS programming model](#).

## 35.5 USB functional description in peripheral mode

The OTG\_HS operates as an USB peripheral in the following circumstances:

- OTG B-device  
OTG B-device default state if the B-side of USB cable is plugged in
- OTG A-device  
OTG A-device state after the HNP switches the OTG\_HS to peripheral role
- B-Device  
If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG\_HS\_GUSBCFG) is cleared (see On-The-Go specification Revision 1.3 section 6.8.3).
- Peripheral only (see [Figure 388: USB peripheral-only connection](#))  
The force peripheral mode bit in the Global USB configuration register (FDMOD in OTG\_HS\_GUSBCFG) is set to 1, forcing the OTG\_HS core to operate in USB peripheral-only mode (see On-The-Go specification Revision 1.3 section 6.8.3). In this case, the ID line is ignored even if it is available on the USB connector.

*Note:* To build a bus-powered device architecture in the B-Device or peripheral-only configuration, an external regulator must be added to generate the  $V_{DD}$  supply voltage from  $V_{BUS}$ .

### 35.5.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG\_HS\_GUSBCFG) configures the OTG\_HS to support the session request protocol (SRP). As a result, it allows the remote A-device to save power by switching  $V_{BUS}$  off when the USB session is suspended.

The SRP peripheral mode program model is described in detail in [Section : B-device session request protocol](#).

## 35.5.2 Peripheral states

### Powered state

The  $V_{BUS}$  input detects the B-session valid voltage used to put the USB peripheral in the Powered state (see USB2.0 specification section 9.1). The OTG\_HS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host, and generates the session request interrupt (SRQINT bit in OTG\_HS\_GINTSTS) to notify the Powered state. The  $V_{BUS}$  input also ensures that valid  $V_{BUS}$  levels are supplied by the host during USB operations. If  $V_{BUS}$  drops below the B-session valid voltage (for example because power disturbances occurred or the host port has been switched off), the OTG\_HS automatically disconnects and the session end detected (SEDET bit in OTG\_HS\_GOTGINT) interrupt is generated to notify that the OTG\_HS has exited the Powered state.

In Powered state, the OTG\_HS expects a reset from the host. No other USB operations are possible. When a reset is received, the reset detected interrupt (USBRST in OTG\_HS\_GINTSTS) is generated. When the reset is complete, the enumeration done interrupt (ENUMDNE bit in OTG\_HS\_GINTSTS) is generated and the OTG\_HS enters the Default state.

### Soft disconnect

The Powered state can be exited by software by using the soft disconnect feature. The DP pull-up resistor is removed by setting the Soft disconnect bit in the device control register (SDIS bit in OTG\_HS\_DCTL), thus generating a device disconnect detection interrupt on the host side even though the USB cable was not really unplugged from the host port.

### Default state

In Default state the OTG\_HS expects to receive a SET\_ADDRESS command from the host. No other USB operations are possible. When a valid SET\_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG\_HS\_DCFG). The OTG\_HS then enters the address state and is ready to answer host transactions at the configured USB address.

### Suspended state

The OTG\_HS peripheral constantly monitors the USB activity. When the USB remains idle for 3 ms, the early suspend interrupt (ESUSP bit in OTG\_HS\_GINTSTS) is issued. It is confirmed 3 ms later, if appropriate, by generating a suspend interrupt (USBSUSP bit in OTG\_HS\_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG\_HS\_DSTS) and the OTG\_HS enters the Suspended state.

The device can also exit from the Suspended state by itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG\_HS\_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG\_HS\_GINTSTS) is generated and the device suspend bit is automatically cleared.

### 35.5.3 Peripheral endpoints

The OTG\_HS core instantiates the following USB endpoints:

- Control endpoint 0

This endpoint is bidirectional and handles control messages only.

It has a separate set of registers to handle IN and OUT transactions, as well as dedicated control (OTG\_HS\_DIEPCTL0/OTG\_HS\_DOEPCTL0), transfer configuration (OTG\_HS\_DIEPTSIZ0/OTG\_HS\_DOEPSIZ0), and status-interrupt (OTG\_HS\_DIEPINTx/OTG\_HS\_DOEPINT0) registers. The bits available inside the control and transfer size registers slightly differ from other endpoints.
- 5 IN endpoints
  - They can be configured to support the isochronous, bulk or interrupt transfer type.
  - They feature dedicated control (OTG\_HS\_DIEPCTLx), transfer configuration (OTG\_HS\_DIEPTSIZx), and status-interrupt (OTG\_HS\_DIEPINTx) registers.
  - The Device IN endpoints common interrupt mask register (OTG\_HS\_DIEPMSK) allows to enable/disable a single endpoint interrupt source on all of the IN endpoints (EP0 included).
  - They support incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG\_HS\_GINTSTS). This interrupt is asserted when there is at least one isochronous IN endpoint for which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_HS\_GINTSTS/EOPF).
- 5 OUT endpoints
  - They can be configured to support the isochronous, bulk or interrupt transfer type.
  - They feature dedicated control (OTG\_HS\_DOEPCTLx), transfer configuration (OTG\_HS\_DOEPSIZx) and status-interrupt (OTG\_HS\_DOEPINTx) registers.
  - The Device Out endpoints common interrupt mask register (OTG\_HS\_DOEPMSK) allows to enable/disable a single endpoint interrupt source on all OUT endpoints (EP0 included).
  - They support incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG\_HS\_GINTSTS). This interrupt is asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG\_HS\_GINTSTS/EOPF).

## Endpoint controls

The following endpoint controls are available through the device endpoint-x IN/OUT control register (DIEPCTLx/DOEPCTLx):

- Endpoint enable/disable
- Endpoint activation in current configuration
- Program the USB transfer type (isochronous, bulk, interrupt)
- Program the supported packet size
- Program the Tx-FIFO number associated with the IN endpoint
- Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
- Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
- Optionally program the NAK bit to always send a negative acknowledge to the host regardless of the FIFO status
- Optionally program the STALL bit to always stall host tokens to that endpoint
- Optionally program the Snoop mode for OUT endpoint where the received data CRC is not checked

## Endpoint transfer

The device endpoint-x transfer size registers (DIEPTSIZx/DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status.

The programming operation must be performed before setting the endpoint enable bit in the endpoint control register.

Once the endpoint is enabled, these fields are read-only as the OTG FS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets constituting the overall transfer size.

## Endpoint status/interrupt

The device endpoint-x interrupt registers (DIEPINTx/DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in the core interrupt register (OEPINT bit in OTG\_HS\_GINTSTS or IEPINT bit in OTG\_HS\_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt register (OTG\_HS\_DAINR) to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINR and GINTSTS registers.

The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer has completed on both the application (AHB) and USB sides
- Setup stage done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge transmitted to the host (isochronous-in only)
- IN token received when Tx-FIFO was empty (bulk-in/interrupt-in only)
- OUT token received when endpoint was not yet enabled
- Babble error condition detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet dropped without generating an interrupt

## 35.6 USB functional description on host mode

This section gives the functional description of the OTG\_HS in the USB host mode. The OTG\_HS works as a USB host in the following circumstances:

- OTG A-host  
OTG A-device default state when the A-side of the USB cable is plugged in
- OTG B-host  
OTG B-device after HNP switching to the host role
- A-device  
If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG\_HS\_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only ([Figure 389: USB host-only connection](#)).  
The force host mode bit in the global USB configuration register (FHMOD bit in OTG\_HS\_GUSBCFG) forces the OTG\_HS core to operate in USB host-only mode. In this case, the ID line is ignored even if it is available on the USB connector. Integrated pull-down resistors are automatically set on the OTG\_HS\_FS\_DP/OTG\_HS\_FS\_DM lines.

**Note:** On-chip 5 V  $V_{BUS}$  generation is not supported. As a result, a charge pump or a basic power switch (if a 5 V supply is available on the application board) must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.

The  $V_{BUS}$  input ensures that valid  $V_{BUS}$  levels are supplied by the charge pump during USB operations while the charge pump overcurrent output can be input to any GPIO pin configured to generate port interrupts. The overcurrent ISR must promptly disable the  $V_{BUS}$  generation.

Figure 411. USB host-only connection

### 35.6.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in OTG\_HS\_GUSBCFG). When the SRP feature is enabled, the host can save power by switching off the  $V_{BUS}$  power while the USB session is suspended. The

SRP host mode program model is described in detail in [Section : A-device session request protocol](#).

## 35.6.2 USB host states

### Host port power

On-chip 5 V  $V_{BUS}$  generation is not supported. As a result, a charge pump or a basic power switch (if a 5 V supply voltage is available on the application board) must be added externally to drive the 5 V  $V_{BUS}$  line. The external charge pump can be driven by any GPIO output. When the application powers on  $V_{BUS}$  through the selected GPIO, it must also set the port power bit in the host port control and status register (PPWR bit in OTG\_HS\_HPRT).

### $V_{BUS}$ valid

When SRP or HNP is enabled the VBUS sensing pin (PB13) pin should be connected to  $V_{BUS}$ . The  $V_{BUS}$  input ensures that valid  $V_{BUS}$  levels are supplied by the charge pump during USB operations. Any unforeseen  $V_{BUS}$  voltage drop below the  $V_{BUS}$  valid threshold (4.25 V) generates an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG\_HS\_GOTGINT). The application must then switch the  $V_{BUS}$  power off and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin (PB13) should not be connected to  $V_{BUS}$ . This pin can be used as GPIO.

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input, and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the  $V_{BUS}$  generation and clear the port power bit.

### Detection of peripheral connection by the host

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG\_HS does not detect a bus connection until the end of the  $V_{BUS}$  sensing ( $V_{BUS}$  over 4.75 V).

When  $V_{BUS}$  is at a valid level and a remote B-device is attached, the OTG\_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG\_HS\_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG\_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG\_HS\_HPRT).

### Detection of peripheral disconnection by the host

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG\_HS\_GINTSTS).

### Host enumeration

After detecting a peripheral connection, the host must start the enumeration process by issuing an USB reset and configuration commands to the new peripheral.

Before sending an USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG\_HS\_GOTGINT), which indicates that the bus is

stable again after the electrical debounce caused by the attachment of a pull-up resistor on OTG\_HS\_FS\_DP (full speed) or OTG\_HS\_FS\_DM (low speed).

The application issues an USB reset (single-ended zero) via the USB by keeping the port reset bit set in the Host port control and status register (PRST bit in OTG\_HS\_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application monitors the time and then clears the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG\_HS\_HPRT) to inform the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG\_HS\_HPRT), and that the host is starting to drive SOFs (full speed) or keep-alive tokens (low speed). The host is then ready to complete the peripheral enumeration by sending peripheral configuration commands.

### Host suspend

The application can decide to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG\_HS\_HPRT). The OTG\_HS core stops sending SOFs and enters the Suspended state.

The Suspended state can be exited on the remote device initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG\_HS\_GINTSTS) is generated upon detection of a remote wake-up event, the port resume bit in the host port control and status register (PRES bit in OTG\_HS\_HPRT) is set, and a resume signaling is automatically issued on the USB. The application must monitor the resume window duration, and then clear the port resume bit to exit the Suspended state and restart the SOF.

If the Suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, monitor the resume window duration and then clear the port resume bit.

### 35.6.3 Host channels

The OTG\_HS core instantiates 12 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 8 transfer requests simultaneously. If more than 8 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support IN/OUT and any type of periodic/nonperiodic transaction. Each host channel has dedicated control (HCCHARx), transfer configuration (HCTSIZx) and status/interrupt (HCINTx) registers with associated mask (HCINTMSKx) registers.

### Host channel controls

The following host channel controls are available through the host channel-x characteristics register (HCCHARx):

- Channel enable/disable
- Program the HS/FS/LS speed of target USB peripheral
- Program the address of target USB peripheral
- Program the endpoint number of target USB peripheral
- Program the transfer IN/OUT direction
- Program the USB transfer type (control, bulk, interrupt, isochronous)
- Program the maximum packet size (MPS)
- Program the periodic transfer to be executed during odd/even frames

### Host channel transfer

The host channel transfer size registers (HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status.

The programming operation must be performed before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled, the packet count field is read-only as the OTG HS core updates it according to the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets constituting the overall transfer size
- Initial data PID

### Host channel status/interrupt

The host channel-x interrupt register (HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG\_HS\_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (HCAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HCAINT and GINTSTS registers. The mask bits for each interrupt source of each channel are also available in the OTG\_HS\_HCINTMSK-x register.

The host core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
- Channel stopped due to transfer completed, USB transaction error or disable command from the application
- Associated transmit FIFO half or completely empty (IN endpoints)
- ACK response received
- NAK response received
- STALL response received
- USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
- Babble error
- Frame overrun
- Data toggle error

### 35.6.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB the transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG\_HS\_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG HS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (HPTXSTS) and nonperiodic transmit FIFO and queue status register (HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx-FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the USB for a maximum of 8 pending periodic transactions plus 8 pending nonperiodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the PTXQSAV bits in the OTG\_HS\_HNPTXSTS register or NPTQSAV bits in the OTG\_HS\_HNPTXSTS register.

## 35.7 SOF trigger

The OTG FS core allows to monitor, track and configure SOF framing in the host and peripheral. It also features an SOF pulse output connectivity.

These capabilities are particularly useful to implement adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs trimming its framing rate according to the requirements of the audio peripheral.

### 35.7.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (FS) or keep-alive (LS) tokens is programmable in the host frame interval register (OTG\_HS\_HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG\_HS\_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (OTG\_HS\_HFNUM).

An SOF pulse signal is generated at any SOF starting token and with a width of 20 HCLK cycles. It can be made available externally on the SOF pin using the SOFOUTEN bit in the global control and configuration register. The SOF pulse is also internally connected to the input trigger of timer 2 (TIM2), so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse. The TIM2 connection is enabled through ITR1\_RMP bits of TIM2\_OR register.

**Figure 412. SOF trigger output to TIM2 ITR1 connection**

### 35.7.2 Peripheral SOFs

In peripheral mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG\_HS\_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG\_HS\_DSTS). An SOF pulse signal with a width of 20 HCLK cycles is also generated and can be made available externally on the SOF pin by using the SOF output enable bit in the global control and configuration register (SOFOUTEN bit in OTG\_HS\_GCCFG). The SOF pulse signal is also internally connected to the TIM2 input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse (see [Figure 412](#)). The TIM2 connection is enabled through ITR1\_RMP bits of TIM2\_OR register.

The end of periodic frame interrupt (GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG\_HS\_DCFG).

This feature can be used to determine if all of the isochronous traffic for that frame is complete.

## 35.8 OTG\_HS low-power modes

[Table 208](#) below defines the STM32 low power modes and their compatibility with the OTG.

**Table 208. Compatibility of STM32 low power modes with the OTG**

| Mode    | Description                                                                                                 | USB compatibility                        |
|---------|-------------------------------------------------------------------------------------------------------------|------------------------------------------|
| Run     | MCU fully active                                                                                            | Required when USB not in suspend state.  |
| Sleep   | USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.                | Available while USB is in suspend state. |
| Stop    | USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept <sup>(1)</sup> . | Available while USB is in suspend state. |
| Standby | Powered-down. The peripheral must be reinitialized after exiting Standby mode.                              | Not compatible with USB applications.    |

1. Within Stop mode there are different possible settings. Some restrictions may also exist, please refer to [Section 5: Power controller \(PWR\)](#) to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.

The power consumption of the OTG PHY is controlled by three bits in the general core configuration register:

- PHY power down (GCCFG/PWRDWN)  
This bit switches on/off the PHY full-speed transceiver module. It must be preliminarily set to allow any USB operation.
- A-VBUS sensing enable (GCCFG/VBUSASEN)  
This bit switches on/off the  $V_{BUS}$  comparators associated with A-device operations. It must be set when in A-device (USB host) mode and during HNP.
- B-VBUS sensing enable (GCCFG/VBUSASEN)  
This bit switches on/off the  $V_{BUS}$  comparators associated with B-device operations. It must be set when in B-device (USB peripheral) mode and during HNP.  
Power reduction techniques are available in the USB suspended state, when the USB session is not yet valid or the device is disconnected.
- Stop PHY clock (STPPCLK bit in OTG\_HS\_PCGCCTL)
  - When setting the stop PHY clock bit in the clock gating control register, most of the clock domain internal to the OTG high-speed core is switched off by clock gating.

The dynamic power consumption due to the USB clock switching activity is cut even if the clock input is kept running by the application

- Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.
- Gate HCLK (GATEHCLK bit in OTG\_HS\_PCGCCTL)
 

When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG\_HS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.
- USB system stop
  - When the OTG\_HS is in USB suspended state, the application can decide to drastically reduce the overall power consumption by shutting down all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the powercontrol system module (PWR).
  - The OTG\_HS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a Device) signaling on the USB.

### 35.9 Dynamic update of the OTG\_HS\_HFIR register

The USB core embeds a dynamic trimming capability of micro-SOF framing period in host mode allowing to synchronize an external device with the micro-SOF frames.

When the OTG\_HS\_HFIR register is changed within a current micro-SOF frame, the SOF period correction is applied in the next frame as described in [Figure 413](#).

**Figure 413. Updating OTG\_HS\_HFIR dynamically**

## 35.10 FIFO RAM allocation

### 35.10.1 Peripheral mode

#### Receive FIFO RAM

For Receive FIFO RAM, the application should allocate RAM for SETUP packets: 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoints. These locations are reserved for SETUP packets and are not used by the core to write any other data.

One location must be allocated for Global OUT NAK. Status information are also written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{Largest Packet Size} / 4) + 1$  must be allocated to receive packets. If a high-bandwidth endpoint or multiple isochronous endpoints are enabled, at least two spaces of  $(\text{Largest Packet Size} / 4) + 1$  must be allotted to receive back-to-back packets. Typically, two  $(\text{Largest Packet Size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to AHB, the USB can receive the subsequent packet.

Along with each endpoints last packet, transfer complete status information are also pushed to the FIFO. Typically, one location for each OUT endpoint is recommended.

#### Transmit FIFO RAM

For Transmit FIFO RAM, the minimum RAM space required for each IN Endpoint Transmit FIFO is the maximum packet size for this IN endpoint.

*Note: More space allocated in the transmit IN Endpoint FIFO results in a better performance on the USB.*

### 35.10.2 Host mode

#### Receive FIFO RAM

For Receive FIFO RAM allocation, Status information are written to the FIFO along with each received packet. Therefore, a minimum space of  $(\text{Largest Packet Size} / 4) + 1$  must be allocated to receive packets. If a high-bandwidth channel or multiple isochronous channels are enabled, at least two spaces of  $(\text{Largest Packet Size} / 4) + 1$  must be allocated to receive back-to-back packets. Typically, two  $(\text{Largest Packet Size} / 4) + 1$  spaces are recommended so that when the previous packet is being transferred to AHB, the USB can receive the subsequent packet.

Along with each host channels last packet, transfer complete status information are also pushed to the FIFO. As a consequence, one location must be allocated to store this data.

#### Transmit FIFO RAM

For Transmit FIFO RAM allocation, the minimum amount of RAM required for the host nonperiodic Transmit FIFO is the largest maximum packet size for all supported nonperiodic OUT channels. Typically, a space corresponding to two Largest Packet Size is recommended, so that when the current packet is being transferred to the USB, the AHB can transmit the subsequent packet.

The minimum amount of RAM required for Host periodic Transmit FIFO is the largest maximum packet size for all supported periodic OUT channels. If there is at least one High

Bandwidth Isochronous OUT endpoint, then the space must be at least two times the maximum packet size for that channel.

*Note: More space allocated in the Transmit nonperiodic FIFO results in better performance on the USB.*

*When operating in DMA mode, the DMA address register for each host channel (HCDMA<sub>n</sub>) is stored in the SPRAM (FIFO). One location for each channel must be reserved for this.*

## 35.11 OTG\_HS interrupts

When the OTG\_HS controller is operating in one mode, either peripheral or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the Core interrupt register (MMIS bit in the OTG\_HS\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 414* shows the interrupt hierarchy.

**Figure 414. Interrupt hierarchy**

1. OTG\_HS\_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.

## 35.12 OTG\_HS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG\_HS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG\_HS registers must be accessed by words (32 bits). CSRs are classified as follows:

- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the Core global, Power and clock-gating, Data FIFO access, and host port control and status registers can be accessed in both host and peripheral modes. When the OTG\_HS controller is operating in one mode, either peripheral or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the Core interrupt register (MMIS bit in the OTG\_HS\_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

### 35.12.1 CSR memory map

The host and peripheral mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

Figure 415. CSR memory map

1. x = 5 in peripheral mode and x = 11 in host mode.

### Global CSR map

These registers are available in both host and peripheral modes.

Table 209. Core global control and status registers (CSRs)

| Acronym        | Address offset | Register name                                                                    |
|----------------|----------------|----------------------------------------------------------------------------------|

### Data FIFO (DFIFO) access register map

These registers, available in both host and peripheral modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Table 212. Data FIFO (DFIFO) access register map

| FIFO access register section                                                                                                                                                              | Address range | Access |

1. Where x is 5 in peripheral mode and 11 in host mode.

### Power and clock gating CSR map

There is a single register for power and clock gating. It is available in both host and peripheral modes.

Table 213. Power and clock gating control and status registers

| Register name                           | Acronym        | Offset address: 0xE00–0xFFF |
|-----------------------------------------|----------------|-----------------------------|
| Power and clock gating control register | OTG_HS_PCGCCTL | 0xE00–0xE04                 |
| Reserved                                | -              | 0xE05–0xFFF                 |

## 35.12.2 OTG\_HS global registers

These registers are available in both host and peripheral modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

### OTG\_HS control and status register (OTG\_HS\_GOTGCTL)

Address offset: 0x000

Reset value: 0x0001 0000

The OTG control and status register controls the behavior and reflects the status of the OTG function of the core.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19    | 18    | 17   | 16     | 15       | 14 | 13 | 12 | 11     | 10      | 9     | 8      | 7        | 6 | 5 | 4 | 3   | 2      | 1 | 0 |

|          |    |    |    |    |    |    |    |    |    |    |    | r     | r     | r    | r      |          |    |    |    | rw     | rw      | rw    | r      |          |   |   |   | rw  | r      |   |   |

Bits 31:20 Reserved, must be kept at reset value.

**Bit 19 BSVLD:** B-session valid

Indicates the peripheral mode transceiver status.

0: B-session is not valid.

1: B-session is valid.

In OTG mode, you can use this bit to determine if the device is connected or disconnected.

*Note: Only accessible in peripheral mode.*

**Bit 18 ASVLD:** A-session valid

Indicates the host mode transceiver status.

0: A-session is not valid

1: A-session is valid

*Note: Only accessible in host mode.*

**Bit 17 DBCT:** Long/short debounce time

Indicates the debounce time of a detected connection.

0: Long debounce time, used for physical connections (100 ms + 2.5  $\mu$ s)

1: Short debounce time, used for soft connections (2.5  $\mu$ s)

*Note: Only accessible in host mode.*

**Bit 16 CIDSTS:** Connector ID status

Indicates the connector ID status on a connect event.

0: The OTG\_HS controller is in A-device mode

1: The OTG\_HS controller is in B-device mode

*Note: Accessible in both peripheral and host modes.*

Bits 15:12 Reserved, must be kept at reset value.

**Bit 11 DHNPEN:** Device HNP enabled

The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.

0: HNP is not enabled in the application

1: HNP is enabled in the application

*Note: Only accessible in peripheral mode.*

**Bit 10 HSHNPEN:** Host set HNP enable

The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.

0: Host Set HNP is not enabled

1: Host Set HNP is enabled

*Note:* Only accessible in host mode.

**Bit 9 HNPRQ:** HNP request

The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG interrupt register (HNSSCHG bit in OTG\_HS\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

0: No HNP request

1: HNP request

*Note:* Only accessible in peripheral mode.

**Bit 8 HNGSCS:** Host negotiation success

The core sets this bit when host negotiation is successful. The core clears this bit when the HNP Request (HNPRQ) bit in this register is set.

0: Host negotiation failure

1: Host negotiation success

*Note:* Only accessible in peripheral mode.

Bits 7:2 Reserved, must be kept at reset value.

**Bit 1 SRQ:** Session request

The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG Interrupt register (HNSSCHG bit in OTG\_HS\_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

If you use the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until  $V_{BUS}$  discharges to 0.2 V, after the B-Session Valid bit in this register (BSVLD bit in OTG\_HS\_GOTGCTL) is cleared.

0: No session request

1: Session request

*Note:* Only accessible in peripheral mode.

**Bit 0 SRQSCS:** Session request success

The core sets this bit when a session request initiation is successful.

0: Session request failure

1: Session request success

*Note:* Only accessible in peripheral mode.

**OTG\_HS interrupt register (OTG\_HS\_GOTGINT)**

Address offset: 0x04

Reset value: 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

|          |    |    |    |    |    |    |    |    |    |    |    | rc_w1  | rc_w1   | rc_w1  |          |    |    |    |    |    |    |   | rc_w1   | rc_w1   |          |   |   |   | rc_w1 |      |   |

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **DBCONE**: Debounce done

The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the Core USB Configuration register (HNPCAP bit or SRPCAP bit in OTG\_HS\_GUSBCFG, respectively).

*Note: Only accessible in host mode.*

Bit 18 **ADTOCHG**: A-device timeout change

The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note: Accessible in both peripheral and host modes.*

Bit 17 **HNGDET**: Host negotiation detected

The core sets this bit when it detects a host negotiation request on the USB.

*Note: Accessible in both peripheral and host modes.*

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **HNSSCHG**: Host negotiation success status change

The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG Control and Status register (HNGSCS in OTG\_HS\_GOTGCTL) to check for success or failure.

*Note: Accessible in both peripheral and host modes.*

Bits 7:3 Reserved, must be kept at reset value.

Bit 8 **SRSSCHG**: Session request success status change

The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG Control and status register (SRQSCS bit in OTG\_HS\_GOTGCTL) to check for success or failure.

*Note: Accessible in both peripheral and host modes.*

Bit 2 **SEDET**: Session end detected

The core sets this bit to indicate that the level of the voltage on  $V_{BUS}$  is no longer valid for a B-device session when  $V_{BUS} < 0.8$  V.

Bits 1:0 Reserved, must be kept at reset value.

**OTG\_HS AHB configuration register (OTG\_HS\_GAHBCFG)**

Address offset: 0x008

Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |          |         |          |       |         |    |    |    |      |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|----------|---------|----------|-------|---------|----|----|----|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8        | 7       | 6        | 5     | 4       | 3  | 2  | 1  | 0    |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   | PTXFELVL | TXFELVL | Reserved | DMAEN | HBSTLEN |    |    |    | GINT |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   | rW       | rW      |          | rW    | rW      | rW | rW | rW | rW   |

Bits 31:20 Reserved, must be kept at reset value.

Bit 8 **PTXFELVL**: Periodic Tx FIFO empty level

Indicates when the periodic Tx FIFO empty interrupt bit in the Core interrupt register (PTXFE bit in OTG\_HS\_GINTSTS) is triggered.

0: PTXFE (in OTG\_HS\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty  
 1: PTXFE (in OTG\_HS\_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

*Note: Only accessible in host mode.*

Bit 7 **TXFELVL**: Tx FIFO empty level

In peripheral mode, this bit indicates when the IN endpoint Transmit FIFO empty interrupt (TXFE in OTG\_HS\_DIEPINTx) is triggered.

0: TXFE (in OTG\_HS\_DIEPINTx) interrupt indicates that the IN Endpoint Tx FIFO is half empty  
 1: TXFE (in OTG\_HS\_DIEPINTx) interrupt indicates that the IN Endpoint Tx FIFO is completely empty

*Note: Only accessible in peripheral mode.*

Bit 6 Reserved, must be kept at reset value.

Bits 5 **DMAEN**: DMA enable

0: The core operates in slave mode  
 1: The core operates in DMA mode

Bits 4:1 **HBSTLEN**: Burst length/type

0000 Single  
 0001 INCR  
 0011 INCR4  
 0101 INCR8  
 0111 INCR16  
 Others: Reserved

Bit 0 **GINT**: Global interrupt mask

This bit is used to mask or unmask the interrupt line assertion to the application. Irrespective of this bit setting, the interrupt status registers are updated by the core.

0: Mask the interrupt assertion to the application.  
 1: Unmask the interrupt assertion to the application

*Note: Accessible in both peripheral and host modes.*

**OTG\_HS USB configuration register (OTG\_HS\_GUSBCFG)**

Address offset: 0x00C

Reset value: 0x0000 1440

This register can be used to configure the core after power-on or a changing to host mode or peripheral mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

| 31     | 30    | 29    | 28       | 27 | 26 | 25 | 24     | 23   | 22   | 21    | 20         | 19         | 18      | 17     | 16      | 15       | 14      | 13       | 12   | 11 | 10 | 9      | 8      | 7        | 6      | 5        | 4 | 3 | 2 | 1     | 0  |    |

Bit 31 **CTXPKT**: Corrupt Tx packet

This bit is for debug purposes only. Never set this bit to 1.

*Note: Accessible in both peripheral and host modes.*

Bit 30 **FDMOD**: Forced peripheral mode

Writing a 1 to this bit forces the core to peripheral mode irrespective of the OTG\_HS\_ID input pin.

0: Normal mode

1: Forced peripheral mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both peripheral and host modes.*

Bit 29 **FHMOD**: Forced host mode

Writing a 1 to this bit forces the core to host mode irrespective of the OTG\_HS\_ID input pin.

0: Normal mode

1: Forced host mode

After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note: Accessible in both peripheral and host modes.*

Bits 28:26 Reserved, must be kept at reset value.

Bit 25 **ULPIPD**: ULPI interface protect disable

This bit controls the circuitry built in the PHY to protect the ULPI interface when the link tri-states stp and data. Any pull-up or pull-down resistors employed by this feature can be disabled. Please refer to the ULPI specification for more details.

0: Enables the interface protection circuit

1: Disables the interface protection circuit

Bit 24 **PTCI**: Indicator pass through

This bit controls whether the complement output is qualified with the internal  $V_{BUS}$  valid comparator before being used in the  $V_{BUS}$  state in the RX CMD. Please refer to the ULPI specification for more details.

0: Complement Output signal is qualified with the Internal  $V_{BUS}$  valid comparator

1: Complement Output signal is not qualified with the Internal  $V_{BUS}$  valid comparator

- Bit 23 **PCCI**: Indicator complement  
 This bit controls the PHY to invert the ExternalVbusIndicator input signal, and generate the complement output. Please refer to the ULPI specification for more details.  
 0: PHY does not invert the ExternalVbusIndicator signal  
 1: PHY inverts ExternalVbusIndicator signal
- Bit 22 **TSDPS**: TermSel DLine pulsing selection  
 This bit selects utmi\_termselect to drive the data line pulse during SRP (session request protocol).  
 0: Data line pulsing using utmi\_txvalid (default)  
 1: Data line pulsing using utmi\_termsel
- Bit 21 **ULPIEBUSI**: ULPI external V<sub>BUS</sub> indicator  
 This bit indicates to the ULPI PHY to use an external V<sub>BUS</sub> overcurrent indicator.  
 0: PHY uses an internal V<sub>BUS</sub> valid comparator  
 1: PHY uses an external V<sub>BUS</sub> valid comparator
- Bit 20 **ULPIEBUSD**: ULPI External V<sub>BUS</sub> Drive  
 This bit selects between internal or external supply to drive 5 V on V<sub>BUS</sub>, in the ULPI PHY.  
 0: PHY drives V<sub>BUS</sub> using internal charge pump (default)  
 1: PHY drives V<sub>BUS</sub> using external supply.
- Bit 19 **ULPICSM**: ULPI Clock SuspendM  
 This bit sets the ClockSuspendM bit in the interface control register on the ULPI PHY. This bit applies only in the serial and carkit modes.  
 0: PHY powers down the internal clock during suspend  
 1: PHY does not power down the internal clock
- Bit 18 **ULPIAR**: ULPI Auto-resume  
 This bit sets the AutoResume bit in the interface control register on the ULPI PHY.  
 0: PHY does not use AutoResume feature  
 1: PHY uses AutoResume feature
- Bit 17 **ULPIFSL**: ULPI FS/LS select  
 The application uses this bit to select the FS/LS serial interface for the ULPI PHY. This bit is valid only when the FS serial transceiver is selected on the ULPI PHY.  
 0: ULPI interface  
 1: ULPI FS/LS serial interface
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **PHYLPCS**: PHY Low-power clock select  
 This bit selects either 480 MHz or 48 MHz (low-power) PHY mode. In FS and LS modes, the PHY can usually operate on a 48 MHz clock to save power.  
 0: 480 MHz internal PLL clock  
 1: 48 MHz external clock  
 In 480 MHz mode, the UTMI interface operates at either 60 or 30 MHz, depending on whether the 8- or 16-bit data width is selected. In 48 MHz mode, the UTMI interface operates at 48 MHz in FS and LS modes.
- Bit 14 Reserved, must be kept at reset value.
- Bits 13:10 **TRDT**: USB turnaround time  
 These bits allow to set the turnaround time in PHY clocks. They must be configured according to [Table 214: TRDT values](#), depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the Data FIFO.

Bit 9 **HNPCAP**: HNP-capable

The application uses this bit to control the OTG\_HS controller's HNP capabilities.

0: HNP capability is not enabled

1: HNP capability is enabled

*Note:* Accessible in both peripheral and host modes.

Bit 8 **SRPCAP**: SRP-capable

The application uses this bit to control the OTG\_HS controller's SRP capabilities. If the core operates as a nonSRP-capable B-device, it cannot request the connected A-device (host) to activate  $V_{BUS}$  and start a session.

0: SRP capability is not enabled

1: SRP capability is enabled

*Note:* Accessible in both peripheral and host modes.

## Bit 7 Reserved, must be kept at reset value.

Bit 6 **PHYSEL**: USB 2.0 high-speed ULPI PHY or USB 1.1 full-speed serial transceiver select

0: USB 2.0 high-speed ULPI PHY

1: USB 1.1 full-speed serial transceiver

## Bits 5:3 Reserved, must be kept at reset value.

Bits 2:0 **TOTAL**: FS timeout calibration

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

Table 214. TRDT values

| AHB frequency range (MHz) |     | TRDT minimum value |
|---------------------------|-----|--------------------|
| Min.                      | Max |                    |
| 30                        | -   | 0x9                |

**OTG\_HS reset register (OTG\_HS\_GRSTCTL)**

Address offset: 0x010

Reset value: 0x8000 0000

The application uses this register to reset various hardware features inside the core.

| 31     | 30     | 29       | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10     | 9  | 8       | 7       | 6        | 5     | 4     | 3     | 2 | 1 | 0 |
|--------|--------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|---------|---------|----------|-------|-------|-------|---|---|---|
| AHBIDL | DMAREQ | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | TXFNUM |    | TXFFLSH | RXFFLSH | Reserved | FCRST | HSRST | CSRST |   |   |   |
| r      | r      |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw     | rs | rs      | rs      |          | rs    |       |       |   |   |   |

**Bit 31 AHBIDL:** AHB master idle

Indicates that the AHB master state machine is in the Idle condition.

*Note:* Accessible in both peripheral and host modes.**Bit 30 DMAREQ:** DMA request signal

This bit indicates that the DMA request is in progress. Used for debug.

**Bits 29:11** Reserved, must be kept at reset value.**Bits 10:6 TXFNUM:** TxFIFO number

This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit.

00000:

- Nonperiodic TxFIFO flush in host mode
- Tx FIFO 0 flush in peripheral mode

00001:

- Periodic TxFIFO flush in host mode
- TXFIFO 1 flush in peripheral mode

00010: TXFIFO 2 flush in peripheral mode

...

00101: TXFIFO 15 flush in peripheral mode

10000: Flush all the transmit FIFOs in peripheral or host mode.

*Note:* Accessible in both peripheral and host modes.**Bit 5 TXFFLSH:** TxFIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers:

- Read: the NAK effective interrupt ensures the core is not reading from the FIFO
- Write: the AHBIDL bit in OTG\_HS\_GRSTCTL ensures that the core is not writing anything to the FIFO

*Note:* Accessible in both peripheral and host modes.

Bit 4 **RXFFLSH**: RxFIFO flush

The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO.

The application must wait until the bit is cleared before performing any other operation. This bit requires 8 clocks (slowest of PHY or AHB clock) to be cleared.

*Note: Accessible in both peripheral and host modes.*

## Bit 3    Reserved, must be kept at reset value.

**Bit 2 FCRST:** Host frame counter reset

The application writes this bit to reset the (micro) frame number counter inside the core. When the (micro) frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.

*Note:* Only accessible in host mode.

**Bit 1 HSRST:** HCLK soft reset

The application uses this bit to flush the control logic in the AHB Clock domain. Only AHB Clock Domain pipelines are reset.

FIFOs are not flushed with this bit.

All state machines in the AHB clock domain are reset to the Idle state after terminating the transactions on the AHB, following the protocol.

CSR control bits used by the AHB clock domain state machines are cleared.

To clear this interrupt, status mask bits that control the interrupt status and are generated by the AHB clock domain state machine are cleared.

Because interrupt status bits are not cleared, the application can get the status of any core events that occurred after it set this bit.

This is a self-clearing bit that the core clears after all necessary logic is reset in the core. This can take several clocks, depending on the core's current state.

*Note:* Accessible in both peripheral and host modes.

**Bit 0 CSRST:** Core soft reset

Resets the HCLK and PCLK domains as follows:

Clears the interrupts and all the CSR register bits except for the following bits:

- RSTPDMODL bit in OTG\_HS\_PCGCCTL
- GAYEHCLK bit in OTG\_HS\_PCGCCTL
- PWRCLMP bit in OTG\_HS\_PCGCCTL
- STPPCLK bit in OTG\_HS\_PCGCCTL
- FSLSPCS bit in OTG\_HS\_HCFG
- DSPD bit in OTG\_HS\_DCFG

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.

The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when you dynamically change the PHY selection bits in the above listed USB configuration registers. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note:* Accessible in both peripheral and host modes.

**OTG\_HS core interrupt register (OTG\_HS\_GINTSTS)**

Address offset: 0x014

Reset value: 0x0400 0020

This register interrupts the application for system-level events in the current mode (peripheral mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in peripheral mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc\_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG\_HS\_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

| 31     | 30     | 29      | 28      | 27       | 26    | 25    | 24      | 23       | 22        | 21                  | 20      | 19     | 18     | 17       | 16 | 15   | 14      | 13      | 12     | 11      | 10    | 9        | 8 | 7        | 6        | 5      | 4      | 3   | 2      | 1    | 0    |  |  |  |  |  |

|        |        |         |         |          |       |       |         |          |           |                     |         |        |        |          |    |      |         |         |        |         |       |          |   |          |          |        |        |     |        |      |      |  |  |  |  |  |

Bit 31 **WKUPINT**: Resume/remote wake-up detected interrupt

In peripheral mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wake-up is detected on the USB.

*Note: Accessible in both peripheral and host modes.*

Bit 30 **SRQINT**: Session request/new session detected interrupt

In host mode, this interrupt is asserted when a session request is detected from the device. In peripheral mode, this interrupt is asserted when  $V_{BUS}$  is in the valid range for a B-device device. Accessible in both peripheral and host modes.

Bit 29 **DISCINT**: Disconnect detected interrupt

Asserted when a device disconnect is detected.

*Note: Only accessible in host mode.*

Bit 28 **CIDSCHG**: Connector ID status change

The core sets this bit when there is a change in connector ID status.

*Note: Accessible in both peripheral and host modes.*

Bit 27 Reserved, must be kept at reset value.

Bit 26 **PTXFE**: Periodic Tx FIFO empty

Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the Core AHB configuration register (PTXFELVL bit in OTG\_HS\_GAHBCFG).

*Note: Only accessible in host mode.*

**Bit 25 HCINT:** Host channels interrupt

The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the host all channels interrupt (OTG\_HS\_HAINT) register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding host channel-x interrupt (OTG\_HS\_HCINTx) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG\_HS\_HCINTx register to clear this bit.

*Note: Only accessible in host mode.*

**Bit 24 HPRTINT:** Host port interrupt

The core sets this bit to indicate a change in port status of one of the OTG\_HS controller ports in host mode. The application must read the host port control and status (OTG\_HS\_HPRT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the host port control and status register to clear this bit.

*Note: Only accessible in host mode.*

Bits 23 Reserved, must be kept at reset value.

**Bit 22 DATAFSUSP:** Data fetch suspended

This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:

- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints
- Clears the global nonperiodic IN NAK handshake If the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an “IN token received when FIFO empty” interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG\_HS\_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the “IN token received when FIFO empty” interrupt when clearing a global IN NAK handshake.

**Bit 21 IPXFR:** Incomplete periodic transfer

In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

*Note: Only accessible in host mode.*

**INCOMPISOOUT:** Incomplete isochronous OUT transfer

In peripheral mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in peripheral mode.*

**Bit 20 IISOIXFR:** Incomplete isochronous IN transfer

The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in peripheral mode.*

**Bit 19 OEPINT:** OUT endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in peripheral mode). The application must read the device all endpoints interrupt (OTG\_HS\_DAIN) register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding device OUT Endpoint-x Interrupt (OTG\_HS\_DOEPINTx) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_HS\_DOEPINTx register to clear this bit.

*Note: Only accessible in peripheral mode.*

**Bit 18 IEPINT:** IN endpoint interrupt

The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in peripheral mode). The application must read the device All Endpoints Interrupt (OTG\_HS\_DAIN) register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding device IN Endpoint-x interrupt (OTG\_HS\_DIEPINTx) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG\_HS\_DIEPINTx register to clear this bit.

*Note: Only accessible in peripheral mode.*

Bits 17:16 Reserved, must be kept at reset value.

**Bit 15 EOPF:** End of periodic frame interrupt

Indicates that the period specified in the periodic frame interval field of the device configuration register (PFIVL bit in OTG\_HS\_DCFG) has been reached in the current frame.

*Note: Only accessible in peripheral mode.*

**Bit 14 ISOODRP:** Isochronous OUT packet dropped interrupt

The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.

*Note: Only accessible in peripheral mode.*

**Bit 13 ENUMDNE:** Enumeration done

The core sets this bit to indicate that speed enumeration is complete. The application must read the device Status (OTG\_HS\_DSTS) register to obtain the enumerated speed.

*Note: Only accessible in peripheral mode.*

**Bit 12 USBRST:** USB reset

The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in peripheral mode.*

**Bit 11 USBSUSP:** USB suspend

The core sets this bit to indicate that a suspend was detected on the USB. The core enters the Suspended state when there is no activity on the data lines for a period of 3 ms.

*Note: Only accessible in peripheral mode.*

**Bit 10 ESUSP:** Early suspend

The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in peripheral mode.*

Bits 9:8 Reserved, must be kept at reset value.

**Bit 7 GONAKEFF:** Global OUT NAK effective

Indicates that the Set global OUT NAK bit in the Device control register (SGONAK bit in OTG\_HS\_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the Device control register (CGONAK bit in OTG\_HS\_DCTL).

*Note: Only accessible in peripheral mode.*

**Bit 6 GINAKEFF:** Global IN nonperiodic NAK effective

Indicates that the Set global nonperiodic IN NAK bit in the Device control register (SGINAK bit in OTG\_HS\_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global nonperiodic IN NAK bit in the Device control register (CGINAK bit in OTG\_HS\_DCTL).

This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note: Only accessible in peripheral mode.*

**Bit 5 NPTXFE:** Nonperiodic TxFIFO empty

This interrupt is asserted when the nonperiodic TxFIFO is either half or completely empty, and there is space in at least one entry to be written to the nonperiodic transmit request queue. The half or completely empty status is determined by the nonperiodic TxFIFO empty level bit in the OTG\_HS\_GAHBCFG register (TXFELVL bit in OTG\_HS\_GAHBCFG).

*Note: Only accessible in host mode.*

**Bit 4 RXFLVL:** RxFIFO nonempty

Indicates that there is at least one packet pending to be read from the RxFIFO.

*Note: Accessible in both host and peripheral modes.*

**Bit 3 SOF:** Start of frame

In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.

In peripheral mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: Accessible in both host and peripheral modes.*

**Bit 2 OTGINT:** OTG interrupt

The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (OTG\_HS\_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG\_HS\_GOTGINT register to clear this bit.

*Note: Accessible in both host and peripheral modes.*

**Bit 1 MMIS:** Mode mismatch interrupt

The core sets this bit when the application is trying to access:

A host mode register, when the core is operating in peripheral mode

A peripheral mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note: Accessible in both host and peripheral modes.*

**Bit 0 CMOD:** Current mode of operation

Indicates the current mode.

0: Peripheral mode

1: Host mode

*Note: Accessible in both host and peripheral modes.*

**OTG\_HS interrupt mask register (OTG\_HS\_GINTMSK)**

Address offset: 0x018

Reset value: 0x0000 0000

This register works with the Core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the Core Interrupt (OTG\_HS\_GINTSTS) register bit corresponding to that interrupt is still set.

0: Masked interrupt

1: Unmasked interrupt

*Note: Accessible in both peripheral and host modes.*

Bit 0 Reserved, must be kept at reset value.

## OTG\_HS Receive status debug read/OTG status read and pop registers (OTG\_HS\_GRXSTSR/OTG\_HS\_GRXSTSP)

Address offset for Read: 0x01C

Address offset for Pop: 0x020

Reset value: 0x0000 0000

A read to the Receive status debug read register returns the contents of the top of the Receive FIFO. A read to the Receive status read and pop register additionally pops the top data entry out of the RxFIFO.

The receive status contents must be interpreted differently in host and peripheral modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the Receive Status FIFO when the Receive FIFO nonempty bit of the Core interrupt register (RXFLVL bit in OTG\_HS\_GINTSTS) is asserted.

### Host mode:

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19 | 18   | 17   | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9     | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

|          |    |    |    |    |    |    |    |    |    |    | r      |    | r    | r    |    |    |    |    |    |    |    | r     |   |   |   |   |   |   |   |   |   |

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **PKTSTS**: Packet status

Indicates the status of the received packet

0010: IN data packet received

0011: IN transfer completed (triggers an interrupt)

0101: Data toggle error (triggers an interrupt)

0111: Channel halted (triggers an interrupt)

Others: Reserved

Bits 16:15 **DPID**: Data PID

Indicates the Data PID of the received packet

00: DATA0

10: DATA1

01: DATA2

11: MDATA

Bits 14:4 **BCNT**: Byte count

Indicates the byte count of the received IN data packet.

Bits 3:0 **CHNUM**: Channel number

Indicates the channel number to which the current received packet belongs.

**Peripheral mode:**

|          |    |    |    |    |    |    |        |    |        |    |      |      |    |    |    |    |    |    |    |    |    |       |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|--------|----|--------|----|------|------|----|----|----|----|----|----|----|----|----|-------|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24     | 23 | 22     | 21 | 20   | 19   | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9     | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

|          |    |    |    |    |    |    | r      |    | r      |    | r    | r    |    |    |    |    |    |    |    |    |    | r     |   |   |   |   |   |   |   |   |   |

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:21 **FRMNUM**: Frame number

This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 **PKTSTS**: Packet status

Indicates the status of the received packet

0001: Global OUT NAK (triggers an interrupt)

0010: OUT data packet received

0011: OUT transfer completed (triggers an interrupt)

0100: SETUP transaction completed (triggers an interrupt)

0110: SETUP data packet received

Others: Reserved

Bits 16:15 **DPID**: Data PID

Indicates the Data PID of the received OUT data packet

00: DATA0

10: DATA1

01: DATA2

11: MDATA

Bits 14:4 **BCNT**: Byte count

Indicates the byte count of the received data packet.

Bits 3:0 **EPNUM**: Endpoint number

Indicates the endpoint number to which the current received packet belongs.

**OTG\_HS Receive FIFO size register (OTG\_HS\_GRXFSIZ)**

Address offset: 0x024

Reset value: 0x0000 0400

The application can program the RAM size that must be allocated to the RxFIFO.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RXFD |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw   |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RXFD**: RxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 1024

The power-on reset value of this register is specified as the largest Rx data FIFO depth.

**OTG\_HS nonperiodic transmit FIFO size/Endpoint 0 transmit FIFO size register (OTG\_HS\_GNPTXFSIZ/OTG\_HS\_TX0FSIZ)**

Address offset: 0x028

Reset value: 0x0000 0200

**Host mode:**

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |         |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:16 **NPTXFD**: Nonperiodic TxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 1024

Bits 15:0 **NPTXFSA**: Nonperiodic transmit RAM start address

This field contains the memory start address for nonperiodic transmit FIFO RAM.

**Peripheral mode:**

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| r/rw  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r/rw   |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:16 **TX0FD**: Endpoint 0 TxFIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 256

Bits 15:0 **TX0FSA**: Endpoint 0 transmit RAM start address

This field contains the memory start address for Endpoint 0 transmit FIFO RAM.

**OTG\_HS nonperiodic transmit FIFO/queue status register (OTG\_HS\_GNPTXSTS)**

Address offset: 0x02C

Reset value: 0x0008 0400

**Note:** *In peripheral mode, this register is not valid.*

This read-only register contains the free space information for the nonperiodic TxFIFO and the nonperiodic transmit request queue.

|          |          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |          |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **NPTXQTOP**: Top of the nonperiodic transmit request queue

Entry in the nonperiodic Tx request queue that is currently being processed by the MAC.

Bits [30:27]: Channel/endpoint number

Bits [26:25]:

- 00: IN/OUT token
- 01: Zero-length transmit packet (device IN/host OUT)
- 10: PING/CSPLIT token
- 11: Channel halt command

Bit [24]: Terminate (last entry for selected channel/endpoint)

Bits 23:16 **NPTQXSAV**: Nonperiodic transmit request queue space available

Indicates the amount of free space available in the nonperiodic transmit request queue. This queue holds both IN and OUT requests in host mode. Peripheral mode has only IN requests.

00: Nonperiodic transmit request queue is full

01: dx1 location available

10: dx2 locations available

*bxn*: dxn locations available ( $0 \leq n \leq dx8$ )

Others: Reserved

Bits 15:0 **NPTXFSAV**: Nonperiodic TxFIFO space available

Indicates the amount of free space available in the nonperiodic TxFIFO.

Values are in terms of 32-bit words.

00: Nonperiodic TxFIFO is full

01: dx1 word available

10: dx2 words available

0xn: dxn words available (where  $0 \leq n \leq dx1024$ )

Others: Reserved

### OTG\_HS general core configuration register (OTG\_HS\_GCCFG)

Address offset: 0x038

Reset value: 0x0000 XXXX

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21         | 20       | 19      | 18       | 17       | 16     | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|----|----|----|----|------------|----------|---------|----------|----------|--------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Reserved |    |    |    |    |    |    |    |    |    | NOVBUSSENS | SOFOUTEN | VBUSSEN | VBUSASEN | I2CPADEN | PWRDWN | Reserved |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    | r/w        | r/w      | r/w     | r/w      | r/w      | r/w    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **NOVBUSSENS**: V<sub>BUS</sub> sensing disable option

When this bit is set, V<sub>BUS</sub> is considered internally to be always at V<sub>BUS</sub> valid level (5 V). This option removes the need for a dedicated V<sub>BUS</sub> pad, and leave this pad free to be used for other purposes such as a shared functionality. V<sub>BUS</sub> connection can be remapped on another general purpose input pad and monitored by software.

This option is only suitable for host-only or device-only applications.

0: V<sub>BUS</sub> sensing available by hardware

1: V<sub>BUS</sub> sensing not available by hardware.

Bit 20 **SOFOUTEN**: SOF output enable

0: SOF pulse not available on PAD

1: SOF pulse available on PAD

Bit 19 **VBUSSEN**: Enable the V<sub>BUS</sub> sensing “B” device

0: V<sub>BUS</sub> sensing “B” disabled

1: V<sub>BUS</sub> sensing “B” enabled

Bit 18 **VBUSASEN**: Enable the V<sub>BUS</sub> sensing “A” device

0: V<sub>BUS</sub> sensing “A” disabled

1: V<sub>BUS</sub> sensing “A” enabled

Bit 17 **I2CPADEN**: Enable I<sup>2</sup>C bus connection for the external I<sup>2</sup>C PHY interface.

0: I<sup>2</sup>C bus disabled

1: I<sup>2</sup>C bus enabled

Bit 16 **PWRDWN**: Power down

Used to activate the transceiver in transmission/reception

0: Power down active

1: Power down deactivated (“Transceiver active”)

Bits 15:0 Reserved, must be kept at reset value.

### OTG\_HS core ID register (OTG\_HS\_CID)

Address offset: 0x03C

Reset value: 0x0000 1100

This is a register containing the Product ID as reset value.

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

| PRODUCT_ID |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **PRODUCT\_ID**: Product ID field

Application-programmable ID field.

### OTG\_HS Host periodic transmit FIFO size register (OTG\_HS\_HPTXFSIZ)

Address offset: 0x100

Reset value: 0x0200 0800

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PTXFD |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | PTXSA |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r     | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r     | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 **PTXFD**: Host periodic Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 512

Bits 15:0 **PTXSA**: Host periodic Tx FIFO start address

The power-on reset value of this register is the sum of the largest Rx data FIFO depth and largest nonperiodic Tx data FIFO depth.

### OTG\_HS device IN endpoint transmit FIFO size register (OTG\_HS\_DIEPTXFx) (x = 1..5, where x is the FIFO\_number)

Address offset:  $0x104 + 0x04 * (x - 1)$

Reset value: 0x02000400

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| INEPTXFD |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | INEPTXSA |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r        | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r        | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 **INEPTXFD**: IN endpoint Tx FIFO depth

This value is in terms of 32-bit words.

Minimum value is 16

Maximum value is 512

The power-on reset value of this register is specified as the largest IN endpoint FIFO number depth.

Bits 15:0 **INEPTXSA**: IN endpoint FIFOx transmit RAM start address

This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.

## 35.12.3 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in peripheral mode, as the results are undefined. Host mode registers can be categorized as follows:

### OTG\_HS host configuration register (OTG\_HS\_HCFG)

Address offset: 0x400

Reset value: 0x0000 0000

This register configures the core after power-on. Do not change to this register after initializing the host.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support

The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

0: HS/FS/LS, based on the maximum speed supported by the connected device

1: FS/LS-only, even if the connected device can support HS (read-only)

Bits 1:0 **FSLSPCS**: FS/LS PHY clock select

When the core is in FS host mode:

01: PHY clock is running at 48 MHz

Others: Reserved

When the core is in LS host mode:

00: Reserved

01: PHY clock is running at 48 MHz.

10: Select 6 MHz PHY clock frequency

11: Reserved

*Note: The FSLSPCS bit must be set on a connection event according to the speed of the connected device. A software reset must be performed after changing this bit.*

**OTG\_HS Host frame interval register (OTG\_HS\_HFIR)**

Address offset: 0x404

Reset value: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG\_HS controller has enumerated.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | FRIVL |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r/w   | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **FRIVL**: Frame interval

The value that the application programs to this field specifies the interval between two consecutive SOFs (FS), micro-SOFs (HS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the Port enable bit of the host port control and status register (PENA bit in OTG\_HS\_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY Clock Select field of the Host configuration register (FSLSPCS in OTG\_HS\_HCFG):

frame duration × PHY clock frequency

– Frame interval = 1 ms × (FRIVL - 1)

*Note: The FRIVL bit can be modified whenever the application needs to change the Frame interval time.*

**OTG\_HS host frame number/frame time remaining register (OTG\_HS\_HFNUM)**

Address offset: 0x408

Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| FTREM |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | FRNUM |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r     | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r     | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 **FTREM**: Frame time remaining

Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0 **FRNUM**: Frame number

This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.

## OTG\_HS\_Host periodic transmit FIFO/queue status register (OTG\_HS\_HPTXSTS)

Address offset: 0x410

Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic TxFIFO and the periodic transmit request queue.

| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23      | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---------|----|----|----|----|----|----|----|---------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| PTXQTOP |    |    |    |    |    |    |    | PTXQSAV |    |    |    |    |    |    |    | PTXFSAVL |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r       | r  | r  | r  | r  | r  | r  | r  | r       | r  | r  | r  | r  | r  | r  | r  | r        | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:24 **PTXQTOP**: Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

Bit [31]: Odd/Even frame

– 0: send in even (micro) frame

– 1: send in odd (micro) frame

Bits [30:27]: Channel/endpoint number

Bits [26:25]: Type

– 00: IN/OUT

– 01: Zero-length packet

– 11: Disable channel command

Bit [24]: Terminate (last entry for the selected channel/endpoint)

Bits 23:16 **PTXQSAV**: Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.

00: Periodic transmit request queue is full

01: dx1 location available

10: dx2 locations available

bxn: dxn locations available ( $0 \leq dxn \leq \text{PTXFD}$ )

Others: Reserved

Bits 15:0 **PTXFSAVL**: Periodic transmit data FIFO space available

Indicates the number of free locations available to be written to in the periodic TxFIFO.

Values are in terms of 32-bit words

0000: Periodic TxFIFO is full

0001: dx1 word available

0010: dx2 words available

bxn: dxn words available (where  $0 \leq dxn \leq \text{dx512}$ )

Others: Reserved

**OTG\_HS Host all channels interrupt register (OTG\_HS\_HAINT)**

Address offset: 0x414

Reset value: 0x0000 000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the Core interrupt register (HCINT bit in OTG\_HS\_GINTSTS). This is shown in [Figure 414](#). There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | HAINT |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r     | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINT**: Channel interrupts

One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15

**OTG\_HS host all channels interrupt mask register (OTG\_HS\_HAINTMSK)**

Address offset: 0x418

Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **HAINTM**: Channel interrupt mask

0: Masked interrupt

1: Unmasked interrupt

One bit per channel: Bit 0 for channel 0, bit 15 for channel 15

**OTG\_HS host port control and status register (OTG\_HS\_HPRT)**

Address offset: 0x440

Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in [Figure 414](#). The rc\_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG\_HS\_GINTSTS). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc\_w1 bits, the application must write a 1 to the bit to clear the interrupt.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18   | 17 | 16    | 15 | 14 | 13 | 12   | 11    | 10 | 9        | 8    | 7     | 6    | 5       | 4    | 3       | 2     | 1     | 0     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|------|----|-------|----|----|----|------|-------|----|----------|------|-------|------|---------|------|---------|-------|-------|-------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | PSPD |    | PTCTL |    |    |    | PPWR | PLSTS |    | Reserved | PRST | PSUSP | PRES | POCCHNG | POCA | PENCHNG | PENA  | PCDET | PCSTS |
|          |    |    |    |    |    |    |    |    |    |    |    |    | r    | r  | rw    | rw | rw | rw | rw   | r     | r  |          | rw   | rs    | rw   | rc_w1   | r    | rc_w1   | rc_w0 | rc_w1 | r     |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **PSPD**: Port speed

Indicates the speed of the device attached to this port.

00: High speed

01: Full speed

10: Low speed

11: Reserved

Bits 16:13 **PTCTL**: Port test control

The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.

0000: Test mode disabled

0001: Test\_J mode

0010: Test\_K mode

0011: Test\_SE0\_NAK mode

0100: Test\_Packet mode

0101: Test\_Force\_Enable

Others: Reserved

Bit 12 **PPWR**: Port power

The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.

0: Power off

1: Power on

Bits 11:10 **PLSTS**: Port line status

Indicates the current logic level USB data lines

Bit [10]: Logic level of OTG\_HS\_FS\_DP

Bit [11]: Logic level of OTG\_HS\_FS\_DM

Bit 9 Reserved, must be kept at reset value.

**Bit 8 PRST:** Port reset

When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.

0: Port not in reset

1: Port in reset

The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.

High speed: 50 ms

Full speed/Low speed: 10 ms

**Bit 7 PSUSP:** Port suspend

The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the Port clock stop bit, which asserts the suspend input pin of the PHY.

The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the Port reset bit or Port resume bit in this register or the Resume/remote wake-up detected interrupt bit or Disconnect detected interrupt bit in the Core interrupt register (WKUINT or DISCINT in OTG\_HS\_GINTSTS, respectively).

0: Port not in Suspend mode

1: Port in Suspend mode

**Bit 6 PRES:** Port resume

The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.

If the core detects a USB remote wake-up sequence, as indicated by the Port resume/remote wake-up detected interrupt bit of the Core interrupt register (WKUINT bit in OTG\_HS\_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.

0: No resume driven

1: Resume driven

**Bit 5 POCCHNG:** Port overcurrent change

The core sets this bit when the status of the Port overcurrent active bit (bit 4) in this register changes.

**Bit 4 POCA:** Port overcurrent active

Indicates the overcurrent condition of the port.

0: No overcurrent condition

1: Overcurrent condition

**Bit 3 PENCHNG:** Port enable/disable change

The core sets this bit when the status of the Port enable bit [2] in this register changes.

Bit 2 **PENA**: Port enable

A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.

0: Port disabled

1: Port enabled

Bit 1 **PCDET**: Port connect detected

The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the Core interrupt register (HPRTINT bit in OTG\_HS\_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status

0: No device is attached to the port

1: A device is attached to the port

### OTG\_HS host channel-x characteristics register (OTG\_HS\_HCCHARx) (x = 0..11, where x = Channel\_number)

Address offset:  $0x500 + 0x20 * x$

Reset value: 0x0000 0000

| 31    | 30    | 29     | 28  | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18    | 17 | 16    | 15       | 14    | 13    | 12 | 11 | 10 | 9     | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |    |  |
|-------|-------|--------|-----|----|----|----|----|----|----|----|----|----|-------|----|-------|----------|-------|-------|----|----|----|-------|----|----|----|----|----|----|----|----|----|----|--|
| CHENA | CHDIS | ODDFRM | DAD |    |    |    |    |    |    |    | MC |    | EPTYP |    | LSDEV | Reserved | EPDIR | EPNUM |    |    |    | MPSIZ |    |    |    |    |    |    |    |    |    |    |  |
| rs    | rs    | rw     | rw  | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw    | rw | rw    |          | rw    | rw    | rw | rw | rw | rw    | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |  |

Bit 31 **CHENA**: Channel enable

This field is set by the application and cleared by the OTG host.

0: Channel disabled

1: Channel enabled

Bit 30 **CHDIS**: Channel disable

The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29 **ODDFRM**: Odd frame

This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.

0: Even (micro) frame

1: Odd (micro) frame

Bits 28:22 **DAD**: Device address

This field selects the specific device serving as the data source or sink.

Bits 21:20 **MC**: Multi Count (MC) / Error Count (EC)

- When the split enable bit (SPLITEN) in the host channel-x split control register (OTG\_HS\_HCSPLTx) is reset (0), this field indicates to the host the number of transactions that must be executed per micro-frame for this periodic endpoint. For nonperiodic transfers, this field specifies the number of packets to be fetched for this channel before the internal DMA engine changes arbitration.
  - 00: Reserved This field yields undefined results
  - 01: 1 transaction
  - b10: 2 transactions to be issued for this endpoint per micro-frame
  - 11: 3 transactions to be issued for this endpoint per micro-frame.
- When the SPLITEN bit is set (1) in OTG\_HS\_HCSPLTx, this field indicates the number of immediate retries to be performed for a periodic split transaction on transaction errors. This field must be set to at least 01.

Bits 19:18 **EPTYP**: Endpoint type

Indicates the transfer type selected.

- 00: Control
- 01: Isochronous
- 10: Bulk
- 11: Interrupt

Bit 17 **LSDEV**: Low-speed device

This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR**: Endpoint direction

Indicates whether the transaction is IN or OUT.

- 0: OUT
- 1: IN

Bits 14:11 **EPNUM**: Endpoint number

Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ**: Maximum packet size

Indicates the maximum packet size of the associated endpoint.

**OTG\_HS host channel-x split control register (OTG\_HS\_HCSPLTx) (x = 0..11, where x = Channel\_number)**Address offset:  $0x504 + 0x20 * x$ 

Reset value: 0x0000 0000

| 31      | 30       | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14      | 13 | 12      | 11 | 10 | 9  | 8  | 7  | 6       | 5  | 4  | 3  | 2  | 1  | 0  |    |
|---------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|---------|----|---------|----|----|----|----|----|---------|----|----|----|----|----|----|----|
| SPLITEN | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    | COMPLSPLT | XACTPOS |    | HUBADDR |    |    |    |    |    | PRTADDR |    |    |    |    |    |    |    |
|         |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rW        | rW      | rW | rW      | rW | rW | rW | rW | rW | rW      | rW | rW | rW | rW | rW | rW | rW |

Bit 31 **SPLITEN**: Split enable

The application sets this bit to indicate that this channel is enabled to perform split transactions.

Bits 30:17 **Reserved**, must be kept at reset value.Bit 16 **COMPLSPLT**: Do complete split

The application sets this bit to request the OTG host to perform a complete split transaction.

Bits 15:14 **XACTPOS**: Transaction position

This field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction.

11: All. This is the entire data payload of this transaction (which is less than or equal to 188 bytes)

10: Begin. This is the first data payload of this transaction (which is larger than 188 bytes)

00: Mid. This is the middle payload of this transaction (which is larger than 188 bytes)

01: End. This is the last payload of this transaction (which is larger than 188 bytes)

Bits 13:7 **HUBADDR**: Hub address

This field holds the device address of the transaction translator's hub.

Bits 6:0 **PRTADDR**: Port address

This field is the port number of the recipient transaction translator.

### OTG\_HS host channel-x interrupt register (OTG\_HS\_HCINTx) (x = 0..11, where x = Channel\_number)

Address offset:  $0x508 + 0x20 * x$

Reset value: 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in [Figure 414](#). The application must read this register when the host channels interrupt bit in the Core interrupt register (HCINT bit in OTG\_HS\_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG\_HS\_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HS\_HAINT and OTG\_HS\_GINTSTS registers.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2      | 1     | 0     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|-------|-------|-------|-------|-------|-------|-------|--------|-------|-------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | DTERR | FRMOR | BBERR | TXERR | NYET  | ACK   | NAK   | STALL | AHBERR | CHH   | XFRC  |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1 | rc_w1  | rc_w1 | rc_w1 |

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERR**: Data toggle error

Bit 9 **FRMOR**: Frame overrun

Bit 8 **BBERR**: Babble error

Bit 7 **TXERR**: Transaction error

Indicates one of the following errors occurred on the USB.

CRC check failure

Timeout

Bit stuff error

False EOP

Bit 6 **NYET**: Response received interrupt

Bit 5 **ACK**: ACK response received/transmitted interrupt

Bit 4 **NAK**: NAK response received interrupt

Bit 3 **STALL**: STALL response received interrupt

Bit 2 **AHBERR**: AHB error

This error is generated only in Internal DMA mode when an AHB error occurs during an AHB read/write operation. The application can read the corresponding DMA channel address register to get the error address.

Bit 1 **CHH**: Channel halted

Indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.

Bit 0 **XFRC**: Transfer completed

Transfer completed normally without any errors.

### OTG\_HS host channel-x interrupt mask register (OTG\_HS\_HCINTMSKx) (x = 0..11, where x = Channel\_number)

Address offset:  $0x50C + 0x20 * x$

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10     | 9      | 8      | 7      | 6    | 5    | 4    | 3      | 2       | 1    | 0    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|--------|--------|--------|------|------|------|--------|---------|------|------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | DTERRM | FRMORM | BBERRM | TXERRM | NYET | ACKM | NAKM | STALLM | AHBERRM | CHHM | XFRM |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r/w    | r/w    | r/w    | r/w    | r/w  | r/w  | r/w  | r/w    | r/w     | r/w  | r/w  |

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DTERRM**: Data toggle error mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 9 **FRMORM**: Frame overrun mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 8 **BBERRM**: Babble error mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 7 **TXERRM**: Transaction error mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 6 **NYET**: response received interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 5 **ACKM**: ACK response received/transmitted interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 4 **NAKM**: NAK response received interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 3 **STALLM**: STALL response received interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 2 **AHBERRM**: AHB error mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 1 **CHHM**: Channel halted mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 0 **XFRM**: Transfer completed mask

- 0: Masked interrupt
- 1: Unmasked interrupt

### OTG\_HS host channel-x transfer size register (OTG\_HS\_HCTSIZx) (x = 0..11, where x = Channel\_number)

Address offset: 0x510 + 0x20 \* x

Reset value: 0x0000 0000

| 31     | 30   | 29 | 28     | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18     | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0 |
|--------|------|----|--------|----|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|
| DOPING | DPID |    | PKTCNT |    |    |    |    |    |    |    |    |    | XFRSIZ |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
|        |      |    |        |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |
| rW     | rW   | rW | rW     | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW     | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |   |

Bit 31 **DOPING**: Do ping

This bit is used only for OUT transfers. Setting this field to 1 directs the host to do PING protocol.

*Note: Do not set this bit for IN transfers. If this bit is set for IN transfers it disables the channel.*

Bits 30:29 **DPID**: Data PID

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

- 00: DATA0
- 01: DATA2
- 10: DATA1
- 11: MDATA (noncontrol)/SETUP (control)

Bits 28:19 **PKTCNT**: Packet count

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).

The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0 **XFRSIZ**: Transfer size

For an OUT, this field is the number of data bytes the host sends during the transfer.

For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and nonperiodic).

**OTG\_HS host channel-x DMA address register (OTG\_HS\_HCDMAx) (x = 0..11, where x = Channel\_number)**Address offset:  $0x514 + 0x20 * x$ 

Reset value: 0x0000 0000

|         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DMAADDR |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW      | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **DMAADDR**: DMA address

This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction.

**35.12.4 Device-mode registers****OTG\_HS device configuration register (OTG\_HS\_DCFG)**

Address offset: 0x800

Reset value: 0x0220 0000

This register configures the core in peripheral mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

|          |    |    |    |    |    |           |    |          |          |    |    |    |    |    |    |    |    |    |       |     |    |    |    |    |    |    |          |          |    |      |    |    |    |    |

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **PERSCHIVL**: Periodic scheduling interval

This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50 or 75% of the (micro)frame.

- When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data
- When no periodic endpoint is active, then the internal DMA engine services nonperiodic endpoints, ignoring this field
- After the specified time within a (micro)frame, the DMA switches to fetching nonperiodic endpoints

00: 25% of (micro)frame

01: 50% of (micro)frame

10: 75% of (micro)frame

11: Reserved

Bits 23:13 Reserved, must be kept at reset value.

**Bits 12:11 PFIVL:** Periodic (micro)frame interval

Indicates the time within a (micro) frame at which the application must be notified using the end of periodic (micro) frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.

00: 80% of the frame interval

01: 85% of the frame interval

10: 90% of the frame interval

11: 95% of the frame interval

**Bits 10:4 DAD:** Device address

The application must program this field after every SetAddress control command.

Bit 3 **Reserved**, must be kept at reset value.

**Bit 2 NZLSOHSK:** Nonzero-length status OUT handshake

The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's Status stage.

1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.

0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

**Bits 1:0 DSPD:** Device speed

Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.

00: High speed

01: Full speed using external ULPI PHY

10: Reserved

11: Full speed using internal embedded PHY

**OTG\_HS device control register (OTG\_HS\_DCTL)**

Address offset: 0x804

Reset value: 0x0000 0000

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11       | 10     | 9      | 8      | 7      | 6    | 5  | 4  | 3      | 2      | 1    | 0      |

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rw       | w      | w      | w      | w      | rw   | rw | rw | r      | r      | rw   | rw     |

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **POPRGDNE**: Power-on programming done

The application uses this bit to indicate that register programming is completed after a wake-up from power down mode.

Bit 10 **CGONAK**: Clear global OUT NAK

Writing 1 to this field clears the Global OUT NAK.

Bit 9 **SGONAK**: Set global OUT NAK

Writing 1 to this field sets the Global OUT NAK.

The application uses this bit to send a NAK handshake on all OUT endpoints.

The application must set this bit only after making sure that the Global OUT NAK effective bit in the Core interrupt register (GONAKEFF bit in OTG\_HS\_GINTSTS) is cleared.

Bit 8 **CGINAK**: Clear global IN NAK

Writing 1 to this field clears the Global IN NAK.

Bit 7 **SGINAK**: Set global IN NAK

Writing 1 to this field sets the Global nonperiodic IN NAK. The application uses this bit to send a NAK handshake on all nonperiodic IN endpoints.

The application must set this bit only after making sure that the Global IN NAK effective bit in the Core interrupt register (GINAKEFF bit in OTG\_HS\_GINTSTS) is cleared.

Bits 6:4 **TCTL**: Test control

000: Test mode disabled

001: Test\_J mode

010: Test\_K mode

011: Test\_SE0\_NAK mode

100: Test\_Packet mode

101: Test\_Force\_Enable

Others: Reserved

Bit 3 **GONSTS**: Global OUT NAK status

0: A handshake is sent based on the FIFO Status and the NAK and STALL bit settings.

1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.

Bit 2 **GINSTS**: Global IN NAK status

0: A handshake is sent out based on the data availability in the transmit FIFO.

1: A NAK handshake is sent out on all nonperiodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1 **SDIS**: Soft disconnect

The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.

0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.

1: The core generates a device disconnect event to the USB host.

Bit 0 **RWUSIG**: Remote wake-up signaling

When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the Suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.

[Table 215](#) contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

**Table 215. Minimum duration for soft disconnect**

| Operating speed | Device state                                    | Minimum duration   |
|-----------------|-------------------------------------------------|--------------------|
| High speed      | Not Idle or Suspended (Performing transactions) | 125 $\mu$ s        |
| Full speed      | Suspended                                       | 1 ms + 2.5 $\mu$ s |
| Full speed      | Idle                                            | 2.5 $\mu$ s        |
| Full speed      | Not Idle or Suspended (Performing transactions) | 2.5 $\mu$ s        |

**OTG\_HS device status register (OTG\_HS\_DSTS)**

Address offset: 0x808

Reset value: 0x0000 0010

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the device all interrupts (OTG\_HS\_DAINTE) register.

|          |    |    |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |          |    |   |   |      |         |   |         |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|----------|----|---|---|------|---------|---|---------|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21    | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11       | 10 | 9 | 8 | 7    | 6       | 5 | 4       | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    | FNSOF |    |    |    |    |    |    |    |    |    | Reserved |    |   |   | EERR | ENUMSPD |   | SUSPSTS |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    | r     | r  | r  | r  | r  | r  | r  | r  | r  | r  |          |    |   |   | r    | r       | r | r       | r | r | r | r |

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:8 **FNSOF**: Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **EERR**: Erratic error

The core sets this bit to report any erratic errors.

Due to erratic errors, the OTG\_HS controller goes into Suspended state and an interrupt is generated to the application with Early suspend bit of the Core interrupt register (ESUSP bit in OTG\_HS\_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD**: Enumerated speed

Indicates the speed at which the OTG\_HS controller has come up after speed detection through a chirp sequence.

00: High speed

01: Reserved

10: Reserved

11: Full speed (PHY clock is running at 48 MHz)

Others: reserved

Bit 0 **SUSPSTS**: Suspend status

In peripheral mode, this bit is set as long as a Suspend condition is detected on the USB.

The core enters the Suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:

- When there is an activity on the USB data lines
- When the application writes to the Remote wake-up signaling bit in the Device control register (RWUSIG bit in OTG\_HS\_DCTL).

## OTG\_HS device IN endpoint common interrupt mask register (OTG\_HS\_DIEPMSK)

Address offset: 0x810

Reset value: 0x0000 0000

This register works with each of the Device IN endpoint interrupt (OTG\_HS\_DIEPINTx) registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG\_HS\_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

### OTG\_HS device OUT endpoint common interrupt mask register (OTG\_HS\_DOEPMASK)

Address offset: 0x814

Reset value: 0x0000 0000

This register works with each of the Device OUT endpoint interrupt (OTG\_HS\_DOEPINTx) registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG\_HS\_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

### OTG\_HS device all endpoints interrupt register (OTG\_HS\_DAIN)

Address offset: 0x818

Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a device all endpoints interrupt register interrupts the application using the Device OUT endpoints interrupt bit or Device IN endpoints interrupt bit of the Core interrupt register (OEPINT or IEPINT in OTG\_HS\_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-x interrupt register (OTG\_HS\_DIEPINTx/OTG\_HS\_DOEPINTx).

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:16 **OEPIINT**: OUT endpoint interrupt bits

One bit per OUT endpoint:

Bit 16 for OUT endpoint 0, bit 31 for OUT endpoint 15

Bits 15:0 **IEPIINT**: IN endpoint interrupt bits

One bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 15 for endpoint 15

### OTG\_HS all endpoints interrupt mask register (OTG\_HS\_DAINTRMSK)

Address offset: 0x81C

Reset value: 0x0000 0000

The device endpoint interrupt mask register works with the device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the device all endpoints interrupt (OTG\_HS\_DAINTR) register bit corresponding to that interrupt is still set.

Bits 31:16 **OEPM**: OUT EP interrupt mask bits

One per OUT endpoint:

Bit 16 for OUT EP 0, bit 19 for OUT EP 3

0: Masked interrupt

1: Unmasked interrupt

Bits 15:0 **IEPM**: IN EP interrupt mask bits

One bit per IN endpoint:

Bit 0 for IN EP 0, bit 3 for IN EP 3

0: Masked interrupt

1: Unmasked interrupt

### OTG\_HS device $V_{BUS}$ discharge time register (OTG\_HS\_DVBUSDIS)

Address offset: 0x0828

Reset value: 0x0000 17D7

This register specifies the  $V_{BUS}$  discharge time after  $V_{BUS}$  pulsing during SRP.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **VBUSDT**: Device  $V_{BUS}$  discharge time

Specifies the  $V_{BUS}$  discharge time after  $V_{BUS}$  pulsing during SRP. This value equals:

$V_{BUS}$  discharge time in PHY clocks / 1 024

Depending on your  $V_{BUS}$  load, this value may need adjusting.

OTG\_HS device V<sub>BUS</sub> pulsing time register (OTG\_HS\_DVBUSPULSE)

Address offset: 0x082C

Reset value: 0x0000 05B8

This register specifies the V<sub>BUS</sub> pulsing time during SRP.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DVBUSP**: Device V<sub>BUS</sub> pulsing time  
Specifies the V<sub>BUS</sub> pulsing time during SRP. This value equals:  
V<sub>BUS</sub> pulsing time in PHY clocks / 1 024

**OTG\_HS Device threshold control register (OTG\_HS\_DTHRCTL)**

Address offset: 0x0830

Reset value: 0x0000 0000

| 31       | 30 | 29 | 28 | 27    | 26       | 25        | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15      | 14       | 13 | 12 | 11 | 10        | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0        |             |
|----------|----|----|----|-------|----------|-----------|----|----|----|----|----|----|----|----|----|---------|----------|----|----|----|-----------|---|---|---|---|---|---|---|---|---|----------|-------------|
| Reserved |    |    |    | ARPEN | Reserved | RXTHRLLEN |    |    |    |    |    |    |    |    |    | RXTHREN | Reserved |    |    |    | TXTHRLLEN |   |   |   |   |   |   |   |   |   | ISOTHREN | NONISOTHREN |
|          |    |    |    | r/w   |          |           |    |    |    |    |    |    |    |    |    | r/w     |          |    |    |    |           |   |   |   |   |   |   |   |   |   | r/w      |             |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **ARPEN**: Arbiter parking enable

This bit controls internal DMA arbiter parking for IN endpoints. When thresholding is enabled and this bit is set to one, then the arbiter parks on the IN endpoint for which there is a token received on the USB. This is done to avoid getting into underrun conditions. By default parking is enabled.

Bit 26 Reserved, must be kept at reset value.

Bits 25: 17 **RXTHRLLEN**: Receive threshold length

This field specifies the receive thresholding size in words. This field also specifies the amount of data received on the USB before the core can start transmitting on the AHB. The threshold length has to be at least eight words. The recommended value for RXTHRLLEN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG\_HS\_GAHBCFG).

Bit 16 **RXTHREN**: Receive threshold enable

When this bit is set, the core enables thresholding in the receive direction.

Bits 15: 11 Reserved, must be kept at reset value.

Bits 10:2 **TXTHRLLEN**: Transmit threshold length

This field specifies the transmit thresholding size in words. This field specifies the amount of data in bytes to be in the corresponding endpoint transmit FIFO, before the core can start transmitting on the USB. The threshold length has to be at least eight words. This field controls both isochronous and nonisochronous IN endpoint thresholds. The recommended value for TXTHRLLEN is to be the same as the programmed AHB burst length (HBSTLEN bit in OTG\_HS\_GAHBCFG).

Bit 1 **ISOTHREN**: ISO IN endpoint threshold enable

When this bit is set, the core enables thresholding for isochronous IN endpoints.

Bit 0 **NONISOTHREN**: Nonisochronous IN endpoints threshold enable

When this bit is set, the core enables thresholding for nonisochronous IN endpoints.

### OTG\_HS device IN endpoint FIFO empty interrupt mask register: (OTG\_HS\_DIEPEMPMSK)

Address offset: 0x834

Reset value: 0x0000 0000

This register is used to control the IN endpoint FIFO empty interrupt generation (TXFE\_OTG\_HS\_DIEPINTx).

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INEPTXFEM**: IN EP Tx FIFO empty interrupt mask bits

These bits act as mask bits for OTG\_HS\_DIEPINTx.

TXFE interrupt one bit per IN endpoint:

Bit 0 for IN endpoint 0, bit 15 for IN endpoint 15

0: Masked interrupt

1: Unmasked interrupt

### OTG\_HS device each endpoint interrupt register (OTG\_HS\_DEACHINT)

Address offset: 0x0838

Reset value: 0x0000 0000

There is one interrupt bit for endpoint 1 IN and one interrupt bit for endpoint 1 OUT.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |         |          |    |    |    |    |    |    |   |   |   |   |   |         |          |   |   |   |

- Bit 31 **EPENA**: Endpoint enable  
 The application sets this bit to start transmitting data on an endpoint.  
 The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
  - Endpoint disabled
  - Transfer completed
- Bit 30 **EPDIS**: Endpoint disable  
 The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint disabled interrupt. The application must set this bit only if Endpoint enable is already set for this endpoint.
- Bit 29 **SODDFRM**: Set odd frame  
 Applies to isochronous IN and OUT endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.
- Bit 28 **SD0PID**: Set DATA0 PID  
 Applies to interrupt/bulk IN endpoints only.  
 Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.
- SEVNFRM**: Set even frame  
 Applies to isochronous IN endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
- Bit 27 **SNACK**: Set NAK  
 A write to this bit sets the NAK bit for the endpoint.  
 Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a Transfer completed interrupt, or after a SETUP is received on the endpoint.
- Bit 26 **CNAK**: Clear NAK  
 A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 **TXFNUM**: TxFIFO number  
 These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.  
 This field is valid only for IN endpoints.
- Bit 21 **STALL**: STALL handshake  
 Applies to noncontrol, nonisochronous IN endpoints only (access type is rw).  
 The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.  
 Applies to control endpoints only (access type is rs).  
 The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.
- Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP**: Endpoint type

This is the transfer type supported by this logical endpoint.

- 00: Control
- 01: Isochronous
- 10: Bulk
- 11: Interrupt

Bit 17 **NAKSTS**: NAK status

It indicates the following:

- 0: The core is transmitting nonNAK handshakes based on the FIFO status.
- 1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

For nonisochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the TxFIFO.

For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the TxFIFO.

Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame

Applies to isochronous IN endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

- 0: Even frame
- 1: Odd frame

**DPID**: Endpoint data PID

Applies to interrupt/bulk IN endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

- 0: DATA0
- 1: DATA1

Bit 15 **USBAEP**: USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ**: Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

## OTG\_HS device control OUT endpoint 0 control register (OTG\_HS\_DOEPCTL0)

Address offset: 0xB00

Reset value: 0x0000 8000

This section describes the device control OUT endpoint 0 control register. Nonzero control endpoints use registers for endpoints 1–15.

| 31    | 30    | 29       | 28 | 27 | 26 | 25   | 24   | 23       | 22 | 21 | 20 | 19 | 18    | 17   | 16    | 15 | 14     | 13       | 12     | 11       | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1     | 0 |
|-------|-------|----------|----|----|----|------|------|----------|----|----|----|----|-------|------|-------|----|--------|----------|--------|----------|----|---|---|---|---|---|---|---|---|-------|---|
| EPENA | EPDIS | Reserved |    |    |    | SNAK | CNAK | Reserved |    |    |    |    | Stall | SNPM | EPTYP |    | NAKSTS | Reserved | USBAEP | Reserved |    |   |   |   |   |   |   |   |   | MPSIZ |   |
| w     | r     |          |    |    |    | w    | w    |          |    |    |    |    | rs    | rw   | r     | r  | r      |          | r      |          |    |   |   |   |   |   |   |   |   | r     | r |

Bit 31 **EPENA**: Endpoint enable

The application sets this bit to start transmitting data on endpoint 0.

The core clears this bit before setting any of the following interrupts on this endpoint:

- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable

The application cannot disable control OUT endpoint 0.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **SNAK**: Set NAK

A write to this bit sets the NAK bit for the endpoint.

Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a Transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK

A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake

The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode

This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP**: Endpoint type

Hardcoded to 2'b00 for control.

Bit 17 **NAKSTS**: NAK status

Indicates the following:

0: The core is transmitting nonNAK handshakes based on the FIFO status.

1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit, the core stops receiving data, even if there is space in the RxFIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint

This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ**: Maximum packet size

The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.

00: 64 bytes

01: 32 bytes

10: 16 bytes

11: 8 bytes

**OTG\_HS device endpoint-x control register (OTG\_HS\_DOEPTCTLx) (x = 1..5, where x = Endpoint\_number)**
Address offset for OUT endpoints:  $0xB00 + 0x20 * x$ 

Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

| 31    | 30    | 29      | 28              | 27   | 26   | 25       | 24 | 23 | 22 | 21 | 20    | 19   | 18    | 17     | 16         | 15     | 14       | 13 | 12 | 11 | 10 | 9     | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

- Bit 31 **EPENA**: Endpoint enable  
 Applies to IN and OUT endpoints.  
 The application sets this bit to start transmitting data on an endpoint.  
 The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
  - Endpoint disabled
  - Transfer completed
- Bit 30 **EPDIS**: Endpoint disable  
 The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint disabled interrupt. The application must set this bit only if Endpoint enable is already set for this endpoint.
- Bit 29 **SODDFRM**: Set odd frame  
 Applies to isochronous OUT endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.
- Bit 28 **SD0PID**: Set DATA0 PID  
 Applies to interrupt/bulk OUT endpoints only.  
 Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.
- SEVNFRM**: Set even frame  
 Applies to isochronous OUT endpoints only.  
 Writing to this field sets the Even/Odd frame (EONUM) field to even frame.
- Bit 27 **SNACK**: Set NAK  
 A write to this bit sets the NAK bit for the endpoint.  
 Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a Transfer Completed interrupt, or after a SETUP is received on the endpoint.
- Bit 26 **CNAK**: Clear NAK  
 A write to this bit clears the NAK bit for the endpoint.
- Bits 25:22 Reserved, must be kept at reset value.
- Bit 21 **STALL**: STALL handshake  
 Applies to noncontrol, nonisochronous OUT endpoints only (access type is rw).  
 The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.
- Bit 20 **SNPM**: Snoop mode  
 This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.
- Bits 19:18 **EPTYP**: Endpoint type  
 This is the transfer type supported by this logical endpoint.
- 00: Control
  - 01: Isochronous
  - 10: Bulk
  - 11: Interrupt

**Bit 17 NAKSTS:** NAK status

Indicates the following:

- 0: The core is transmitting nonNAK handshakes based on the FIFO status.
- 1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet.

Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

**Bit 16 EONUM:** Even/odd frame

Applies to isochronous IN and OUT endpoints only.

Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

- 0: Even frame
- 1: Odd frame

**DPID:** Endpoint data PID

Applies to interrupt/bulk OUT endpoints only.

Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

- 0: DATA0
- 1: DATA1

**Bit 15 USBAEP:** USB active endpoint

Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

**Bits 10:0 MPSIZ:** Maximum packet size

The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### OTG\_HS device endpoint-x interrupt register (OTG\_HS\_DIEPINTx) (x = 0..5, where x = Endpoint\_number)

Address offset:  $0x908 + 0x20 * x$

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 414](#). The application must read this register when the IN endpoints interrupt bit of the Core interrupt register (IEPINT in OTG\_HS\_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG\_HS\_DAINTE) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HS\_DAINTE and OTG\_HS\_GINTSTS registers.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13  | 12       | 11 | 10        | 9        | 8 | 7     | 6 | 5          | 4     | 3      | 2      | 1      | 0     |        |        |      |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|----------|----|-----------|----------|---|-------|---|------------|-------|--------|--------|--------|-------|--------|--------|------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | NAK | Reserved |    | PKTDRPSTS | Reserved |   |       |   | TXFIFOUDRN | TXFE  | INEPNE | INEPNM | ITTXFE | TOC   | AHBERR | EPDISD | XFRC |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     | rc_w1    |    |           | rc_w1    |   | rc_w1 | r | rc_w1      | rc_w1 | rc_w1  | rc_w1  | rc_w1  | rc_w1 | rc_w1  |        |      |

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK interrupt

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **PKTDRPSTS**: Packet dropped status

This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **TXFIFOUDRN**: Transmit Fifo Underrun (TxfifoUndrn) The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint.

**Dependency:** This interrupt is valid only when Thresholding is enabled

Bit 7 **TXFE**: Transmit FIFO empty

This interrupt is asserted when the TxFIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the TxFIFO empty level bit in the Core AHB configuration register (TXFELVL bit in OTG\_HS\_GAHBCFG).

Bit 6 **INEPNE**: IN endpoint NAK effective

This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG\_HS\_DIEPCTLx.

This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.

This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

- Bit 5 **INEPNM**: IN token received with EP mismatch  
Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.
- Bit 4 **ITTXFE**: IN token received when TxFIFO is empty  
Applies to nonperiodic IN endpoints only.  
Indicates that an IN token was received when the associated TxFIFO (periodic/nonperiodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.
- Bit 3 **TOC**: Timeout condition  
Applies only to Control IN endpoints.  
Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.
- Bit 2 **AHBERR**: AHB error  
This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.
- Bit 1 **EPDISD**: Endpoint disabled interrupt  
This bit indicates that the endpoint is disabled per the application's request.
- Bit 0 **XFRC**: Transfer completed interrupt  
This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

### OTG\_HS device endpoint-x interrupt register (OTG\_HS\_DOEPINTx) (x = 0..5, where x = Endpoint\_number)

Address offset: 0xB08 + 0x20 \* x

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in [Figure 414](#). The application must read this register when the OUT Endpoints Interrupt bit of the Core interrupt register (OEPINT bit in OTG\_HS\_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG\_HS\_DAINTE) register to get the exact endpoint number for the device Endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG\_HS\_DAINTE and OTG\_HS\_GINTSTS registers.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14    | 13    | 12    | 11       | 10 | 9 | 8         | 7        | 6       | 5        | 4       | 3     | 2      | 1     | 0     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|-------|-------|----------|----|---|-----------|----------|---------|----------|---------|-------|--------|-------|-------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | NYET  | NAK   | BERR  | Reserved |    |   | OUTPKTERR | Reserved | B2BSTUP | Reserved | OTEPDIS | STUP  | AHBERR | EPDIS | XFRM  |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rc_w1 | rc_w1 | rc_w1 |          |    |   | rc_w1     |          | rc_w1   |          | rc_w1   | rc_w1 | rc_w1  | rc_w1 | rc_w1 |

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **NYET**: NYET interrupt

The core generates this interrupt when a NYET response is transmitted for a nonisochronous OUT endpoint.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **OUTPKTERR**: OUT packet error

This interrupt is asserted when the core detects an overflow or a CRC error for an OUT packet. This interrupt is valid only when thresholding is enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **B2BSTUP**: Back-to-back SETUP packets received

Applies to Control OUT endpoint only.  
This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled

Applies only to control OUT endpoint.  
Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done

Applies to control OUT endpoints only.

Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 **AHBERR**: AHB error

This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt

This bit indicates that the endpoint is disabled per the application's request.

Bit 0 **XFRC**: Transfer completed interrupt

This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.

**OTG\_HS device IN endpoint 0 transfer size register (OTG\_HS\_DIEPTSIZ0)**

Address offset: 0x910

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG\_HS\_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–15.

|          |    |    |    |    |    |    |    |    |    |    |        |    |          |    |    |    |    |    |    |    |    |   |   |        |    |    |    |    |    |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|--------|----|----------|----|----|----|----|----|----|----|----|---|---|--------|----|----|----|----|----|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19 | 18       | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7      | 6  | 5  | 4  | 3  | 2  | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    | PKTCNT |    | Reserved |    |    |    |    |    |    |    |    |   |   | XFRSIZ |    |    |    |    |    |   |   |
|          |    |    |    |    |    |    |    |    |    |    | rw     | rw |          |    |    |    |    |    |    |    |    |   |   | rw     | rw | rw | rw | rw | rw |   |   |

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:19 **PKTCNT**: Packet count

Indicates the total number of USB packets that constitute the Transfer Size amount of data for endpoint 0.

This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

**OTG\_HS device OUT endpoint 0 transfer size register (OTG\_HS\_DOEPTSIZE0)**

Address offset: 0xB10

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the Endpoint enable bit in the device control endpoint 0 control registers (EPENA bit in OTG\_HS\_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–15.

| 31       | 30      | 29 | 28       | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6      | 5  | 4  | 3  | 2  | 1  | 0  |
|----------|---------|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|--------|----|----|----|----|----|----|
| Reserved | STUPCNT |    | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   | XFRSIZ |    |    |    |    |    |    |
|          | rw      | rw |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   | rw     | rw | rw | rw | rw | rw | rw |

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **STUPCNT**: SETUP packet count

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bits 28:20 Reserved, must be kept at reset value.

Bit 19 **PKTCNT**: Packet count

This field is decremented to zero after a packet is written into the RxFIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ**: Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.

### OTG\_HS device endpoint-x transfer size register (OTG\_HS\_DIEPTSIZx) (x = 1..5, where x = Endpoint\_number)

Address offset: 0x910 + 0x20 \* x

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the Endpoint enable bit in the device endpoint-x control registers (EPENA bit in OTG\_HS\_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **MCNT**: Multi count

For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.

01: 1 packet

10: 2 packets

11: 3 packets

Bit 28:19 **PKTCNT**: Packet count

Indicates the total number of USB packets that constitute the Transfer Size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is read from the TxFIFO.

Bits 18:0 **XFRSIZ**: Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet from the external memory is written to the TxFIFO.

### OTG\_HS device IN endpoint transmit FIFO status register (OTG\_HS\_DTXFSTSx) (x = 0..5, where x = Endpoint\_number)

Address offset for IN endpoints: 0x918 + 0x20 + x

This read-only register contains the free space information for the Device IN endpoint TxFIFO.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | INEPTFSAV |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | r         | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

31:16 Reserved, must be kept at reset value.

15:0 **INEPTFSAV**: IN endpoint TxFIFO space avail ()

Indicates the amount of free space available in the Endpoint TxFIFO.

Values are in terms of 32-bit words:

0x0: Endpoint TxFIFO is full

0x1: 1 word available

0x2: 2 words available

0xn: n words available (0 < n < 512)

Others: Reserved

### OTG\_HS device endpoint-x transfer size register (OTG\_HS\_DOEPTSIZx) (x = 1..5, where x = Endpoint\_number)

Address offset: 0xB10 + 0x20 \* x

Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the device endpoint-x control registers (EPENA bit in OTG\_HS\_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the Endpoint enable bit.

|          | r/rw               | r/rw | rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **RXDPID**: Received data PID (access type is "r")

Applies to isochronous OUT endpoints only.

This is the data PID received in the last packet for this endpoint.

00: DATA0

01: DATA2

10: DATA1

11: MDATA

**STUPCNT**: SETUP packet count (access type is "rw")

Applies to control OUT Endpoints only.

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet

10: 2 packets

11: 3 packets

Bit 28:19 **PKTCNT**: Packet count

Indicates the total number of USB packets that constitute the Transfer Size amount of data for this endpoint.

This field is decremented every time a packet (maximum size or short packet) is written to the RxFIFO.

Bits 18:0 **XFRSIZ**: Transfer size

This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the RxFIFO and written to the external memory.

### OTG\_HS device endpoint-x DMA address register (OTG\_HS\_DIEPDMAx / OTG\_HS\_DOEPDMAx) (x = 0..5, where x = Endpoint\_number)

Address offset for IN endpoints:  $0x914 + 0x20 * x$

Reset value: 0XXXXX XXXX

Address offset for OUT endpoints:  $0xB14 + 0x20 * x$

Reset value: 0XXXXX XXXX

| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| DMAADDR |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw      | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DMAADDR**: DMA address

This bit holds the start address of the external memory for storing or fetching endpoint data.

*Note: For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a word-aligned address.*

### 35.12.5 OTG\_HS power and clock gating control register (OTG\_HS\_PCGCCTL)

Address offset: 0xE00

Reset value: 0x0000 0000

This register is available in host and peripheral modes.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3       | 2        | 1        | 0       |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---------|----------|----------|---------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | PHYSUSP | Reserved | GATEHCLK | STPPCLK |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | r/w     |          | r/w      | r/w     |

Bit 31:5 Reserved, must be kept at reset value.

Bit 4 **PHYSUSP**: PHY suspended

Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit (bit 0).

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK**: Gate HCLK

The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK**: Stop PHY clock

The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.

### 35.12.6 OTG\_HS register map

The table below gives the USB OTG register map and reset values.

**Table 216. OTG\_HS register map and reset values**

| Offset | Register        | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19     | 18      | 17     | 16       | 15       | 14 | 13 | 12     | 11     | 10      | 9     | 8        | 7        | 6        | 5 | 4 | 3 | 2     | 1    | 0      |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 35.13 OTG\_HS programming model

### 35.13.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the Core interrupt register (CMOD bit in OTG\_HS\_GINTSTS) reflects the mode. The OTG\_HS controller enters host mode when an “A” plug is connected or peripheral mode when a “B” plug is connected.

This section explains the initialization of the OTG\_HS controller after power-on. The application must follow the initialization sequence irrespective of host or peripheral mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the Global AHB configuration (OTG\_HS\_GAHBCFG) register:
  - DMA mode bit
  - AHB burst length field
  - Global interrupt mask bit GINT = 1
  - RxFIFO nonempty (RXFLVL bit in OTG\_HS\_GINTSTS)
  - Periodic TxFIFO empty level
2. Program the following fields in OTG\_HS\_GUSBCFG register:
  - HNP capable bit
  - SRP capable bit
  - FS timeout calibration field
  - USB turnaround time field
3. The software must unmask the following bits in the GINTMSK register:  
OTG interrupt mask  
Mode mismatch interrupt mask
4. The software can read the CMOD bit in OTG\_HS\_GINTSTS to determine whether the OTG\_HS controller is operating in host or peripheral mode.

### 35.13.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in GINTMSK to unmask
2. Program the OTG\_HS\_HCFG register to select full-speed host
3. Program the PPWR bit in OTG\_HS\_HPRT to 1. This drives  $V_{BUS}$  on the USB.
4. Wait for the PCDET interrupt in OTG\_HS\_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG\_HS\_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG\_HS\_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG\_HS\_HPRT.
9. Read the PSPD bit in OTG\_HS\_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1.
11. Program the FLSPCS field in OTG\_HS\_HCFG register according to the speed of the detected device read in step 9. If FLSPCS has been changed, reset the port.
12. Program the OTG\_HS\_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG\_HS\_GNPTXFSIZ register to select the size and the start address of the nonperiodic transmit FIFO for nonperiodic transactions.
14. Program the OTG\_HS\_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

### 35.13.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG\_HS\_DCFG register:
  - Device speed
  - Nonzero-length status OUT handshake
2. Program the OTG\_HS\_GINTMSK register to unmask the following interrupts:
  - USB reset
  - Enumeration done
  - Early suspend
  - USB suspend
  - SOF
3. Program the VBUSSEN bit in the OTG\_HS\_GCCFG register to enable  $V_{BUS}$  sensing in “B” peripheral mode and supply the 5 volts across the pull-up resistor on the DP line.
4. Wait for the USBRST interrupt in OTG\_HS\_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.

Wait for the ENUMDNE interrupt in OTG\_HS\_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG\_HS\_DSTS register to determine the enumeration speed and perform the steps listed in [Endpoint initialization on enumeration completion on page 1519](#).

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

### 35.13.4 DMA mode

The OTG host uses the AHB master interface to fetch the transmit packet data (AHB to USB) and receive the data update (USB to AHB). The AHB master uses the programmed DMA address (HCDMAx register in host mode and DIEPDMAx/DOEPDMAx register in peripheral mode) to access the data buffers.

### 35.13.5 Host programming model

#### Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the GINTMSK register to unmask the following:
2. Channel interrupt
  - Nonperiodic transmit FIFO empty for OUT transactions (applicable for Slave mode that operates in pipelined transaction-level with the packet count field programmed with more than one).
  - Nonperiodic transmit FIFO half-empty for OUT transactions (applicable for Slave mode that operates in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG\_HS\_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG\_HS\_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG\_HS\_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the selected channels in the OTG\_HS\_HCSPLTx register(s) with the hub and port addresses (split transactions only).
7. Program the selected channels in the HCDMAx register(s) with the buffer start address.
8. Program the OTG\_HS\_HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).

### Halting a channel

The application can disable any channel by programming the OTG\_HS\_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG\_HS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG\_HS\_HCINTx before reallocating the channel for other transactions. The OTG\_HS host does not interrupt the transaction that has already been started on the USB.

To disable a channel in DMA mode operation, the application does not need to check for space in the request queue. The OTG\_HS host checks for space to write the disable request on the disabled channel's turn during arbitration. Meanwhile, all posted requests are dropped from the request queue when the CHDIS bit in HCCHARx is set to 1.

Before disabling a channel, the application must ensure that there is at least one free space available in the nonperiodic request queue (when disabling a nonperiodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the Request queue is full (before disabling the channel), by programming the OTG\_HS\_HCCHARx register with the CHDIS bit set to 1, and the CHENA bit cleared to 0.

The application is expected to disable a channel on any of the following conditions:

1. When an XFRC interrupt in OTG\_HS\_HCINTx is received during a nonperiodic IN transfer or high-bandwidth interrupt IN transfer (Slave mode only)
2. When an STALL, TXERR, BBERR or DTERR interrupt in OTG\_HS\_HCINTx is received for an IN or OUT channel (Slave mode only). For high-bandwidth interrupt INs in Slave mode, once the application has received a DTERR interrupt it must disable the

channel and wait for a channel halted interrupt. The application must be able to receive other interrupts (DTERR, NAK, Data, TXERR) for the same channel before receiving the halt.

3. When a DISCINT (Disconnect Device) interrupt in OTG\_HS\_GINTSTS is received. (The application is expected to disable all enabled channels)
4. When the application aborts a transfer before normal completion.

### Ping protocol

When the OTG\_HS host operates in high speed, the application must initiate the ping protocol when communicating with high-speed bulk or control (data and status stage) OUT endpoints.

The application must initiate the ping protocol when it receives a NAK/NYET/TXERR interrupt. When the HS\_OTG host receives one of the above responses, it does not continue any transaction for a specific endpoint, drops all posted or fetched OUT requests (from the request queue), and flushes the corresponding data (from the transmit FIFO).

This is valid in slave mode only. In Slave mode, the application can send a ping token either by setting the DOPING bit in HCTSIZx before enabling the channel or by just writing the HCTSIZx register with the DOPING bit set when the channel is already enabled. This enables the HS\_OTG host to write a ping request entry to the request queue. The application must wait for the response to the ping token (a NAK, ACK, or TXERR interrupt) before continuing the transaction or sending another ping token. The application can continue the data transaction only after receiving an ACK from the OUT endpoint for the requested ping. In DMA mode operation, the application does not need to set the DOPING bit in HCTSIZx for a NAK/NYET response in case of Bulk/Control OUT. The OTG\_HS host automatically sets the DOPING bit in HCTSIZx, and issues the ping tokens for Bulk/Control OUT. The HS\_OTG host continues sending ping tokens until it receives an ACK, and then switches automatically to the data transaction.

### Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**

The OTG\_HS host automatically writes an entry (OUT request) to the periodic/nonperiodic request queue, along with the last word write of a packet. The application must ensure that at least one free space is available in the periodic/nonperiodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in words. If the packet size is non-word-aligned, the application must use padding. The OTG\_HS host determines the actual packet size based on the programmed maximum packet size and transfer size.

Figure 416. Transmit FIFO write task

- **Reading the receive FIFO**

The application must ignore all packet statuses other than IN data packet (bx0010).

**Figure 417. Receive FIFO read task**

- **Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in [Figure 418](#). See channel 1 (ch\_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The nonperiodic transmit FIFO can hold two packets (128 bytes for FS).
- The nonperiodic request queue depth = 4.

- **Normal bulk and control OUT/SETUP operations**

The sequence of operations for channel 1 is as follows:

- Initialize channel 1
- Write the first packet for channel 1

- c) Along with the last word write, the core writes an entry to the nonperiodic request queue
- d) As soon as the nonperiodic queue becomes nonempty, the core attempts to send an OUT token in the current frame
- e) Write the second (last) packet for channel 1
- f) The core generates the XFRC interrupt as soon as the last transaction is completed successfully
- g) In response to the XFRC interrupt, de-allocate the channel for other transfers
- h) Handling nonACK responses

**Figure 418. Normal bulk/control OUT/SETUP and bulk/control IN transactions - DMA mode**

**Figure 419. Normal bulk/control OUT/SETUP and bulk/control IN transactions - Slave mode**

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in Slave mode is shown in the following code samples.

- Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**

a) Bulk/Control OUT/SETUP

```
Unmask (NAK/TXERR/STALL/XFRC)
if (XFRC)
{
    Reset Error Count
}
```

```

    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask CHH
    Disable Channel
}
else if (NAK or TXERR )
{
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

The application is expected to write the data packets into the transmit FIFO as and when the space is available in the transmit FIFO and the Request queue. The application can make use of the NPTXFE interrupt in OTG\_HS\_GINTSTS to find the transmit FIFO space.

b) Bulk/Control IN

```

Unmask (TXERR/XFRC/BBERR/STALL/DTERR)
if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
}

```

```

    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DTERR)
{
    Reset Error Count
}

```

The application is expected to write the requests as and when the Request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**

A typical bulk or control IN pipelined transaction-level operation is shown in [Figure 420](#). See channel 2 (ch\_2). The assumptions are:

- The application is attempting to receive two maximum-packet-size packets (transfer size = 1 024 bytes).
- The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (72 bytes for FS).
- The nonperiodic request queue depth = 4.

Figure 420. Bulk/control IN transactions - DMA mode

Figure 421. Bulk/control IN transactions - Slave mode

The sequence of operations is as follows:

- Initialize channel 2.
- Set the CHENA bit in HCCHAR2 to write an IN request to the nonperiodic request queue.
- The core attempts to send an IN token after completing the current OUT transaction.
- The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
- In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the

receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.

- f) The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
  - g) The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR  $\neq$  0b0010).
  - h) The core generates the XFRC interrupt as soon as the receive packet status is read.
  - i) In response to the XFRC interrupt, disable the channel and stop writing the OTG\_HS\_HCCHAR2 register for further requests. The core writes a channel disable request to the nonperiodic request queue as soon as the OTG\_HS\_HCCHAR2 register is written.
  - j) The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
  - k) Read and ignore the receive packet status.
  - l) The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
  - m) In response to the CHH interrupt, de-allocate the channel for other transfers.
  - n) Handling nonACK responses
- **Control transactions in slave mode**  
Setup, Data, and Status stages of a control transfer must be performed as three separate transfers. Setup-, Data- or Status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or Status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in OTG\_HS\_HCCHAR1 to Control. During the Setup stage, the application is expected to set the PID field in OTG\_HS\_HCTSIZ1 to SETUP.
  - **Interrupt OUT transactions**  
A typical interrupt OUT operation in Slave mode is shown in [Figure 422](#). The assumptions are:
    - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
    - The periodic transmit FIFO can hold one packet (1 KB)
    - Periodic request queue depth = 4
 The sequence of operations is as follows:
    - a) Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_HS\_HCCHAR1.
    - b) Write the first packet for channel 1. For a high-bandwidth interrupt transfer, the application must write the subsequent packets up to MCNT (maximum number of packets to be transmitted in the next frame times) before switching to another channel.
    - c) Along with the last word write of each packet, the OTG\_HS host writes an entry to the periodic request queue.
    - d) The OTG\_HS host attempts to send an OUT token in the next (odd) frame.
    - e) The OTG\_HS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
    - f) In response to the XFRC interrupt, reinitialize the channel for the next transfer.

Figure 422. Normal interrupt OUT/IN transactions - DMA mode

Figure 423. Normal interrupt OUT/IN transactions - Slave mode

- Interrupt service routine for interrupt OUT/IN transactions

- a) Interrupt OUT

**Unmask (NAK/TXERR/STALL/XFRC/FRMOR)**

**if (XFRC)**

```
{
  Reset Error Count
  Mask ACK
  De-allocate Channel
}
```

**else**

```
  if (STALL or FRMOR)
  {
```

```

Mask ACK
Unmask CHH
Disable Channel
if (STALL)
{
    Transfer Done = 1
}
}
else
if (NAK or TXERR)
{
    Rewind Buffer Pointers
    Reset Error Count
    Mask ACK
    Unmask CHH
    Disable Channel
}
else
if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel (in next b_interval - 1 Frame)
    }
}
else
if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the Request queue up to the count specified in the MCNT field before switching to another channel. The application uses the NPTXFE interrupt in OTG\_HS\_GINTSTS to find the transmit FIFO space.

b) Interrupt IN

```

Unmask (NAK/TXERR/XFRC/BBERR/STALL/FRMOR/DTERR)
if (XFRC)
{
    Reset Error Count
    Mask ACK
    if (OTG_HS_HCTSIZx.PKTCNT == 0)
    {
        De-allocate Channel
    }
    else
    {

```

```
        Transfer Done = 1
        Unmask CHH
        Disable Channel
    }
}
else
    if (STALL or FRMOR or NAK or DTERR or BBERR)
    {
        Mask ACK
        Unmask CHH
        Disable Channel
        if (STALL or BBERR)
        {
            Reset Error Count
            Transfer Done = 1
        }
        else
            if (!FRMOR)
            {
                Reset Error Count
            }
    }
else
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
        Unmask CHH
        Disable Channel
    }
else
    if (CHH)
    {
        Mask CHH
        if (Transfer Done or (Error_count == 3))
        {
            De-allocate Channel
        }
        else
            Re-initialize Channel (in next b_interval - 1 /Frame)
    }
}
else
    if (ACK)
    {
        Reset Error Count
        Mask ACK
```

}

The application is expected to write the requests for the same channel when the Request queue space is available up to the count specified in the MCNT field before switching to another channel (if any).

- **Interrupt IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
- Periodic request queue depth = 4.

- **Normal interrupt IN operation**

The sequence of operations is as follows:

- Initialize channel 2. The application must set the ODDFRM bit in OTG\_HS\_HCCHAR2.
- Set the CHENA bit in OTG\_HS\_HCCHAR2 to write an IN request to the periodic request queue. For a high-bandwidth interrupt transfer, the application must write the OTG\_HS\_HCCHAR2 register MCNT (maximum number of expected packets in the next frame times) before switching to another channel.
- The OTG\_HS host writes an IN request to the periodic request queue for each OTG\_HS\_HCCHAR2 register write with the CHENA bit set.
- The OTG\_HS host attempts to send an IN token in the next (odd) frame.
- As soon as the IN packet is received and written to the receive FIFO, the OTG\_HS host generates an RXFLVL interrupt.
- In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
- The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
- The core generates an XFRC interrupt as soon as the receive packet status is read.
- In response to the XFRC interrupt, read the PKTCNT field in OTG\_HS\_HCTSIZ2. If the PKTCNT bit in OTG\_HS\_HCTSIZ2 is not equal to 0, disable the channel before re-initializing the channel for the next transfer, if any). If PKTCNT bit in

OTG\_HS\_HCTSIZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_HS\_HCCHAR2.

- **Isochronous OUT transactions**

A typical isochronous OUT operation in Slave mode is shown in [Figure 424](#). The assumptions are:

- The application is attempting to send one packet every frame (up to 1 maximum packet size), starting with an odd frame. (transfer size = 1 024 bytes).
- The periodic transmit FIFO can hold one packet (1 KB).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

- a) Initialize and enable channel 1. The application must set the ODDFRM bit in OTG\_HS\_HCCHAR1.
- b) Write the first packet for channel 1. For a high-bandwidth isochronous transfer, the application must write the subsequent packets up to MCNT (maximum number of packets to be transmitted in the next frame times before switching to another channel).
- c) Along with the last word write of each packet, the OTG\_HS host writes an entry to the periodic request queue.
- d) The OTG\_HS host attempts to send the OUT token in the next frame (odd).
- e) The OTG\_HS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
- f) In response to the XFRC interrupt, reinitialize the channel for the next transfer.
- g) Handling nonACK responses

}
```

- **Isochronous IN transactions**

The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

- Initialize channel 2. The application must set the ODDFRM bit in OTG\_HS\_HCCHAR2.
- Set the CHENA bit in OTG\_HS\_HCCHAR2 to write an IN request to the periodic request queue. For a high-bandwidth isochronous transfer, the application must write the OTG\_HS\_HCCHAR2 register MCNT (maximum number of expected packets in the next frame times) before switching to another channel.
- The OTG\_HS host writes an IN request to the periodic request queue for each OTG\_HS\_HCCHAR2 register write with the CHENA bit set.
- The OTG\_HS host attempts to send an IN token in the next odd frame.
- As soon as the IN packet is received and written to the receive FIFO, the OTG\_HS host generates an RXFLVL interrupt.
- In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
- The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG\_HS\_GRXSTSR ≠ 0b0010).
- The core generates an XFRC interrupt as soon as the receive packet status is read.
- In response to the XFRC interrupt, read the PKTCNT field in OTG\_HS\_HCTSIZ2. If PKTCNT ≠ 0 in OTG\_HS\_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG\_HS\_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG\_HS\_HCCHAR2.

- **Selecting the queue depth**

Choose the periodic and nonperiodic request queue depths carefully to match the number of periodic/nonperiodic endpoints accessed.

The nonperiodic request queue depth affects the performance of nonperiodic transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline nonperiodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core's periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a micro-frame. In Slave mode, however, the application must also take into account the disable entry that must be put into the queue. So, if there are two nonhigh-bandwidth periodic endpoints, the periodic request queue depth must be at least 4. If at least one high-bandwidth endpoint is supported, the queue depth must be

8. If the periodic request queue depth is smaller than the periodic transfers scheduled in a micro-frame, a frame overrun condition occurs.

- **Handling babble conditions**

OTG\_HS controller handles two cases of babble: packet babble and port babble.

Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When OTG\_HS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

When OTG\_HS controller detects a port babble, it flushes the RxFIFO and disables the port. The core then generates a Port disabled interrupt (HPRTINT in OTG\_HS\_GINTSTS, PENCHNG in OTG\_HS\_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the Port Disabled interrupt) by checking POCA in OTG\_HS\_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

- **Bulk and control OUT/SETUP transactions in DMA mode**

The sequence of operations is as follows:

- Initialize and enable channel 1 as explained in [Section : Channel initialization](#).
- The HS\_OTG host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the OTG\_HS host uses the programmed DMA address to fetch the packet.
- After fetching the last word of the second (last) packet, the OTG\_HS host masks channel 1 internally for further arbitration.
- The HS\_OTG host generates a CHH interrupt as soon as the last packet is sent.
- In response to the CHH interrupt, de-allocate the channel for other transfers.

- **NAK and NYET handling with internal DMA**

- The OTG\_HS host sends a bulk OUT transaction.
- The device responds with NAK or NYET.
- If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding the buffer pointers and re-initializing the Channel without application intervention.
- The core automatically issues a ping token.
- When the device returns an ACK, the core continues with the transfer. Optionally, the application can utilize these interrupts, in which case the NAK or NYET interrupt is masked by the application.

The core does not generate a separate interrupt when NAK or NYET is received by the host functionality.

- **Bulk and control IN transactions in DMA mode**

The sequence of operations is as follows:

- Initialize and enable the used channel (channel x) as explained in [Section : Channel initialization](#).
- The OTG\_HS host writes an IN request to the request queue as soon as the channel receives the grant from the arbiter (arbitration is performed in a round-robin fashion).

- c) The OTG\_HS host starts writing the received data to the system memory as soon as the last byte is received with no errors.
- d) When the last packet is received, the OTG\_HS host sets an internal flag to remove any extra IN requests from the request queue.
- e) The OTG\_HS host flushes the extra requests.
- f) The final request to disable channel x is written to the request queue. At this point, channel 2 is internally masked for further arbitration.
- g) The OTG\_HS host generates the CHH interrupt as soon as the disable request comes to the top of the queue.
- h) In response to the CHH interrupt, de-allocate the channel for other transfers.
- **Interrupt OUT transactions in DMA mode**
  - a) Initialize and enable channel x as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last word fetch. In high-bandwidth transfers, the HS\_OTG host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
  - c) The OTG\_HS host attempts to send the OUT token at the beginning of the next odd frame/micro-frame.
  - d) After successfully transmitting the packet, the OTG\_HS host generates a CHH interrupt.
  - e) In response to the CHH interrupt, reinitialize the channel for the next transfer.
- **Interrupt IN transactions in DMA mode**

The sequence of operations (channelx) is as follows:

  - a) Initialize and enable channel x as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG\_HS host writes consecutive writes up to MC times.
  - c) The OTG\_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
  - d) As soon the packet is received and written to the receive FIFO, the OTG\_HS host generates a CHH interrupt.
  - e) In response to the CHH interrupt, reinitialize the channel for the next transfer.
- **Isochronous OUT transactions in DMA mode**
  - a) Initialize and enable channel x as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last word fetch. In high-bandwidth transfers, the OTG\_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
  - c) The OTG\_HS host attempts to send an OUT token at the beginning of the next (odd) frame/micro-frame.
  - d) After successfully transmitting the packet, the HS\_OTG host generates a CHH interrupt.
  - e) In response to the CHH interrupt, reinitialize the channel for the next transfer.
- **Isochronous IN transactions in DMA mode**

The sequence of operations ((channel x) is as follows:

- a) Initialize and enable channel x as explained in [Section : Channel initialization](#).
- b) The OTG\_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG\_HS host performs consecutive write operations up to MC times.
- c) The OTG\_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
- d) As soon the packet is received and written to the receive FIFO, the OTG\_HS host generates a CHH interrupt.
- e) In response to the CHH interrupt, reinitialize the channel for the next transfer.
- **Bulk and control OUT/SETUP split transactions in DMA mode**

The sequence of operations in (channel x) is as follows:

  - a) Initialize and enable channel x for start split as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last word fetch.
  - c) After successfully transmitting start split, the OTG\_HS host generates the CHH interrupt.
  - d) In response to the CHH interrupt, set the COMPLSPLT bit in HCSPLT1 to send the complete split.
  - e) After successfully transmitting complete split, the OTG\_HS host generates the CHH interrupt.
  - f) In response to the CHH interrupt, de-allocate the channel.
- **Bulk/Control IN split transactions in DMA mode**

The sequence of operations (channel x) is as follows:

  - a) Initialize and enable channel x as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host writes the start split request to the nonperiodic request after getting the grant from the arbiter. The OTG\_HS host masks the channel x internally for the arbitration after writing the request.
  - c) As soon as the IN token is transmitted, the OTG\_HS host generates the CHH interrupt.
  - d) In response to the CHH interrupt, set the COMPLSPLT bit in HCSPLT2 and re-enable the channel to send the complete split token. This unmask channel x for arbitration.
  - e) The OTG\_HS host writes the complete split request to the nonperiodic request after receiving the grant from the arbiter.
  - f) The OTG\_HS host starts writing the packet to the system memory after receiving the packet successfully.
  - g) As soon as the received packet is written to the system memory, the OTG\_HS host generates a CHH interrupt.
  - h) In response to the CHH interrupt, de-allocate the channel.
- **Interrupt OUT split transactions in DMA mode**

The sequence of operations in (channel x) is as follows:

  - a) Initialize and enable channel 1 for start split as explained in [Section : Channel initialization](#). The application must set the ODDFRM bit in HCCHAR1.
  - b) The HS\_OTG host starts reading the packet.

- c) The HS\_OTG host attempts to send the start split transaction.
- d) After successfully transmitting the start split, the OTG\_HS host generates the CHH interrupt.
- e) In response to the CHH interrupt, set the COMPLSPLT bit in HCSPLT1 to send the complete split.
- f) After successfully completing the complete split transaction, the OTG\_HS host generates the CHH interrupt.
- g) In response to CHH interrupt, de-allocate the channel.
- **Interrupt IN split transactions in DMA mode**

The sequence of operations in (channel x) is as follows:

  - a) Initialize and enable channel x for start split as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  - c) The OTG\_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  - d) The OTG\_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  - e) In response to the CHH interrupt, set the COMPLSPLT bit in HCSPLT2 to send the complete split.
  - f) As soon as the packet is received successfully, the OTG\_HS host starts writing the data to the system memory.
  - g) The OTG\_HS host generates the CHH interrupt after transferring the received data to the system memory.
  - h) In response to the CHH interrupt, de-allocate or reinitialize the channel for the next start split.
- **Isochronous OUT split transactions in DMA mode**

The sequence of operations (channel x) is as follows:

  - a) Initialize and enable channel x for start split (begin) as explained in [Section : Channel initialization](#). The application must set the ODDFRM bit in HCCHAR1. Program the MPS field.
  - b) The HS\_OTG host starts reading the packet.
  - c) After successfully transmitting the start split (begin), the HS\_OTG host generates the CHH interrupt.
  - d) In response to the CHH interrupt, reinitialize the registers to send the start split (end).
  - e) After successfully transmitting the start split (end), the OTG\_HS host generates a CHH interrupt.
  - f) In response to the CHH interrupt, de-allocate the channel.
- **Isochronous IN split transactions in DMA mode**

The sequence of operations (channel x) is as follows:

  - a) Initialize and enable channel x for start split as explained in [Section : Channel initialization](#).
  - b) The OTG\_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.

- c) The OTG\_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
- d) The OTG\_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
- e) In response to the CHH interrupt, set the COMPLSPLT bit in HCSPLT2 to send the complete split.
- f) As soon as the packet is received successfully, the OTG\_HS host starts writing the data to the system memory.
- g) The OTG\_HS host generates the CHH interrupt after transferring the received data to the system memory. In response to the CHH interrupt, de-allocate the channel or reinitialize the channel for the next start split.

### 35.13.6 Device programming model

#### Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
  - SNAK = 1 in OTG\_HS\_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
  - INEP0 = 1 in OTG\_HS\_DAINMSK (control 0 IN endpoint)
  - OUTEP0 = 1 in OTG\_HS\_DAINMSK (control 0 OUT endpoint)
  - STUP = 1 in DOEPMSK
  - XFRC = 1 in DOEPMSK
  - XFRC = 1 in DIEPMSK
  - TOC = 1 in DIEPMSK
3. Set up the Data FIFO RAM for each of the FIFOs
  - Program the OTG\_HS\_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
  - Program the OTG\_HS\_TX0FSIZ register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
  - STUPCNT = 3 in OTG\_HS\_DOEPSIZ0 (to receive up to 3 back-to-back SETUP packets)
5. In DMA mode, the DOEPDMA0 register should have a valid memory address to store any SETUP packets received.

At this point, all initialization required to receive SETUP packets is done.

**Endpoint initialization on enumeration completion**

1. On the Enumeration Done interrupt (ENUMDNE in OTG\_HS\_GINTSTS), read the OTG\_HS\_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG\_HS\_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
3. In DMA mode, program the DOEPTL0 register to enable control OUT endpoint 0, to receive a SETUP packet.
  - EPENA bit in DOEPTL0 = 1

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

**Endpoint initialization on SetAddress command**

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG\_HS\_DCFG register with the device address received in the SetAddress command
1. Program the core to send out a status IN packet

**Endpoint initialization on SetConfiguration/SetInterface command**

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG\_HS\_DAINMSK register.
5. Set up the Data FIFO RAM for each FIFO.
6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

### Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG\_HS\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_HS\_DOEPCTLx register (for OUT or bidirectional endpoints).
  - Maximum packet size
  - USB active endpoint = 1
  - Endpoint start data toggle (for interrupt and bulk endpoints)
  - Endpoint type
  - TxFIFO number
2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

### Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG\_HS\_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG\_HS\_DOEPCTLx register (for OUT or bidirectional endpoints).
2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

*Note:* The application must meet the following conditions to set up the device core to handle traffic:  
NPTXFEM and RXFLVLM in GINTMSK must be cleared.

## 35.13.7 Operational model

### SETUP and OUT data transfers

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

- **Packet read**

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO in Slave mode.

1. On catching an RXFLVL interrupt (OTG\_HS\_GINTSTS register), the application must read the Receive status pop register (OTG\_HS\_GRXSTSP).
2. The application can mask the RXFLVL interrupt (in OTG\_HS\_GINTSTS) by writing to RXFLVL = 0 (in GINTMSK), until it has read the packet from the receive FIFO.
3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive Data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.

4. The receive FIFO packet status readout indicates one of the following:
  - a) Global OUT NAK pattern:  
PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = Don't Care (0x0),  
DPID = Don't Care (0b00).  
These data indicate that the global OUT NAK bit has taken effect.
  - b) SETUP packet pattern:  
PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num, DPID = D0.  
These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
  - c) Setup stage done pattern:  
PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num,  
DPID = Don't Care (0b00).  
These data indicate that the Setup stage for the specified endpoint has completed and the Data stage has started. After this entry is popped from the receive FIFO, the core asserts a Setup interrupt on the specified control OUT endpoint.
  - d) Data OUT packet pattern:  
PKTSTS = DataOUT, BCNT = size of the received data OUT packet  
( $0 \leq \text{BCNT} \leq 1024$ ), EPNUM = EPNUM on which the packet was received,  
DPID = Actual Data PID.
  - e) Data transfer completed pattern:  
PKTSTS = Data OUT Transfer Done, BCNT = 0x0, EPNUM = OUT EP Num  
on which the data transfer is complete, DPID = Don't Care (0b00).  
These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a Transfer Completed interrupt on the specified OUT endpoint.
5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG\_HS\_GINTSTS) must be unmasked.
6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG\_HS\_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

*Figure 426* provides a flowchart of the above procedure.

Figure 426. Receive FIFO packet read in slave mode

- **SETUP transactions**

This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

- **Application requirements**

1. To receive a SETUP packet, the STUPCNT field (OTG\_HS\_DOEPTSIZx) in a control OUT endpoint must be programmed to a nonzero value. When the application programs the STUPCNT field to a nonzero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG\_HS\_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the Setup stage of a control transfer.
  - STUPCNT = 3 in OTG\_HS\_DOEPTSIZx
2. The application must always allocate some extra space in the Receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
  - The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the Setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
  - 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (Setup packet pattern). The core reserves this space in the receive data.
  - FIFO to write SETUP data only, and never uses this space for data packets.

3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the Setup stage done word from the receive FIFO.
- **Internal data flow**
5. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
  - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
6. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
  - The first word contains control information used internally by the core
  - The second word contains the first 4 bytes of the SETUP command
  - The third word contains the last 4 bytes of the SETUP command
7. When the Setup stage changes to a Data IN/OUT stage, the core writes an entry (Setup stage done word) to the receive FIFO, indicating the completion of the Setup stage.
8. On the AHB side, SETUP packets are emptied by the application.
9. When the application pops the Setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG\_HS\_DOEPINTx), indicating it can process the received SETUP packet.
  - The core clears the endpoint enable bit for control OUT endpoints.
- **Application programming sequence**
1. Program the OTG\_HS\_DOEPTSIZx register.
  - STUPCNT = 3
2. Wait for the RXFLVL interrupt (OTG\_HS\_GINTSTS) and empty the data packets from the receive FIFO.
3. Assertion of the STUP interrupt (OTG\_HS\_DOEPINTx) marks a successful completion of the SETUP Data Transfer.
  - On this interrupt, the application must read the OTG\_HS\_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.

Figure 427. Processing a SETUP packet

- **Handling more than three back-to-back SETUP packets**

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG\_HS controller generates an interrupt (B2BSTUP in OTG\_HS\_DOEPINTx).

- **Setting the global OUT NAK**

Internal data flow:

1. When the application sets the Global OUT NAK (SGONAK bit in OTG\_HS\_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, nonisochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG\_HS\_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG\_HS\_DCTL.

Application programming sequence:

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
  - SGONAK = 1 in OTG\_HS\_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG\_HS\_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG\_HS\_DCTL and before the core asserts the GONAKEFF interrupt (OTG\_HS\_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GINAKEFFM bit in GINTMSK.
  - GINAKEFFM = 0 in GINTMSK
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG\_HS\_DCTL. This also clears the GONAKEFF interrupt (OTG\_HS\_GINTSTS).
  - OTG\_HS\_DCTL = 1 in CGONAK
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
  - GINAKEFFM = 1 in GINTMSK

- **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:

1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
  - SGONAK = 1 in OTG\_HS\_DCTL
2. Wait for the GONAKEFF interrupt (OTG\_HS\_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
  - EPDIS = 1 in OTG\_HS\_DOEPCTLx
  - SNAK = 1 in OTG\_HS\_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG\_HS\_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
  - EPDIS = 0 in OTG\_HS\_DOEPCTLx
  - EPENA = 0 in OTG\_HS\_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other nondisabled OUT endpoints.
  - SGONAK = 0 in OTG\_HS\_DCTL

- **Transfer Stop Programming for OUT endpoints**

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

**Sequence of operations:**

1. Enable all OUT endpoints by setting
  - EPENA = 1 in all OTG\_HS\_DOEPCTLx registers.
2. Flush the RxFIFO as follows
  - Poll OTG\_HS\_GRSTCTL.AHBIDL until it is 1. This indicates that AHB master is idle.
  - Perform read modify write operation on OTG\_HS\_GRSTCTL.RXFFLSH = 1
  - Poll OTG\_HS\_GRSTCTL.RXFFLSH until it is 0, but also using a timeout of less than 10 milli-seconds (corresponds to minimum reset signaling duration). If 0 is seen before the timeout, then the RxFIFO flush is successful. If at the moment the timeout occurs, there is still a 1, (this may be due to a packet on EP0 coming from the host) then go back (once only) to the previous step (“Perform read modify write operation”).
3. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in [“Setting the global OUT NAK on page 1524”](#). This ensures that data in the RxFIFO is sent to the application successfully. Set SGONAK = 1 in OTG\_HS\_DCTL
4. Wait for the GONAKEFF interrupt (OTG\_HS\_GINTSTS)
5. Disable all active OUT endpoints by programming the following register bits:
  - EPDIS = 1 in registers OTG\_HS\_DOEPCTLx
  - SNAK = 1 in registers OTG\_HS\_DOEPCTLx
6. Wait for the EPDIS interrupt in OTG\_HS\_DOEPINTx for each OUT endpoint programmed in the previous step. The EPDIS interrupt in OTG\_HS\_DOEPINTx indicates that the corresponding OUT endpoint is completely disabled. When the EPDIS interrupt is asserted, the following bits are cleared:
  - EPENA = 0 in registers OTG\_HS\_DOEPCTLx
  - EPDIS = 0 in registers OTG\_HS\_DOEPCTLx
  - SNAK = 0 in registers OTG\_HS\_DOEPCTLx

• **Generic non-isochronous OUT data transfers**

This section describes a regular nonisochronous OUT data transfer (control, bulk, or interrupt).

Application requirements:

1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.
2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
  - $\text{transfer size}[\text{EPNUM}] = n \times (\text{MPSIZ}[\text{EPNUM}] + 4 - (\text{MPSIZ}[\text{EPNUM}] \bmod 4))$
  - $\text{packet count}[\text{EPNUM}] = n$
  - $n > 0$
3. On any OUT endpoint interrupt, the application must read the endpoint’s transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
  - $\text{Payload size in memory} = \text{application programmed initial transfer size} - \text{core updated final transfer size}$
  - $\text{Number of USB packets in which this payload was received} = \text{application programmed initial packet count} - \text{core updated final packet count}$

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
  - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
  - After sending an ACK for the packet on the USB, the core discards nonisochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
  - If there is no space in the receive FIFO, isochronous or nonisochronous data packets are ignored and not written to the receive FIFO. Additionally, nonisochronous OUT tokens receive a NAK handshake reply.
  - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or nonisochronous data packets are ignored and not written to the receive FIFO, and nonisochronous OUT tokens receive a NAK handshake reply.
4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
  - The transfer size is 0 and the packet count is 0
  - The last OUT data packet written to the receive FIFO is a short packet ( $0 \leq \text{packet size} < \text{maximum packet size}$ )
7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG\_HS\_DOEPTSIZE register for the transfer size and the corresponding packet count.
2. Program the OTG\_HS\_DOEPCTL register with the endpoint characteristics, and set the EPENA and CNAK bits.
  - EPENA = 1 in OTG\_HS\_DOEPCTL
  - CNAK = 1 in OTG\_HS\_DOEPCTL
3. Wait for the RXFLVL interrupt (in OTG\_HS\_GINTSTS) and empty the data packets from the receive FIFO.
  - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG\_HS\_DOEPINT) marks a successful completion of the nonisochronous OUT data transfer.
5. Read the OTG\_HS\_DOEPTSIZE register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**

This section describes a regular isochronous OUT data transfer.

Application requirements:

1. All the application requirements for nonisochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG\_HS\_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG\_HS\_GINTSTS) and before the SOF (OTG\_HS\_GINTSTS).

Internal data flow:

1. The internal data flow for isochronous OUT endpoints is the same as that for nonisochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
  - EONUM (in OTG\_HS\_DOEPCTL) = SOFFN[0] (in OTG\_HS\_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG\_HS\_DOEPTSIZE with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:

1. Program the OTG\_HS\_DOEPTSIz register for the transfer size and the corresponding packet count
2. Program the OTG\_HS\_DOEPCTLx register with the endpoint characteristics and set the Endpoint Enable, ClearNAK, and Even/Odd frame bits.
  - EPENA = 1
  - CNAK = 1
  - EONUM = (0: Even/1: Odd)
3. In Slave mode, wait for the RXFLVL interrupt (in OTG\_HS\_GINTSTS) and empty the data packets from the receive FIFO
  - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG\_HS\_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the IISOXFRM interrupt in OTG\_HS\_GINTSTS.
6. Read the OTG\_HS\_DOEPTSIz register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
  - RXDPID = D0 (in OTG\_HS\_DOEPTSIz) and the number of USB packets in which this payload was received = 1
  - RXDPID = D1 (in OTG\_HS\_DOEPTSIz) and the number of USB packets in which this payload was received = 2
  - RXDPID = D2 (in OTG\_HS\_DOEPTSIz) and the number of USB packets in which this payload was received = 3

The number of USB packets in which this payload was received =  
Application programmed initial packet count – Core updated final packet count

The application can discard invalid data packets.

• **Incomplete isochronous OUT data transfers**

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal data flow:

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG\_HS\_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application could fail to detect the XFRC interrupt (OTG\_HS\_DOEPINTx) under the following circumstances:
  - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
  - When the isochronous OUT data packet is received with CRC errors
  - When the isochronous OUT token received by the core is corrupted
  - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete Isochronous OUT data interrupt (IISOXFRM in OTG\_HS\_GINTSTS), indicating that an XFRC interrupt (in OTG\_HS\_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:

1. Asserting the IISOXFRM interrupt (OTG\_HS\_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
  - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG\_HS\_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.
3. When it receives an IISOXFRM interrupt (in OTG\_HS\_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG\_HS\_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current micro-frame. An endpoint transfer is incomplete if both the following conditions are met:
  - EONUM bit (in OTG\_HS\_DOEPCTLx) = SOFFN[0] (in OTG\_HS\_DSTS)
  - EPENA = 1 (in OTG\_HS\_DOEPCTLx)
4. The previous step must be performed before the SOF interrupt (in OTG\_HS\_GINTSTS) is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG\_HS\_DOEPCTLx.
6. Wait for the EPDIS interrupt (in OTG\_HS\_DOEPINTx) and enable the endpoint to receive new data in the next frame.
  - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

- **Stalling a nonisochronous OUT endpoint**

This section describes how the application can stall a nonisochronous endpoint.

1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
  - When disabling the endpoint, instead of setting the SNAK bit in OTG\_HS\_DOEPCTL, set STALL = 1 (in OTG\_HS\_DOEPCTL).  
The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG\_HS\_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

## Examples

This section describes and depicts some fundamental transfer types and scenarios.

- Slave mode bulk OUT transaction

*Figure 428* depicts the reception of a single Bulk OUT Data packet from the USB to the AHB and describes the events involved in the process.

Figure 428. Slave mode bulk OUT transaction

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG\_HS\_DOEPCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG\_HS\_DOEPSIZx register.

1. Host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG\_HS\_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG\_HS\_DOEPINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG\_HS\_DOEPINTx) to determine that the intended transfer is complete.

## IN data transfers

### • Packet write

This section describes how the application writes data packets to the endpoint FIFO in Slave mode when dedicated transmit FIFOs are enabled.

1. The application can either choose the polling or the interrupt mode.
  - In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG\_HS\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - In interrupt mode, the application waits for the TXFE interrupt (in OTG\_HS\_DIEPINTx) and then reads the OTG\_HS\_DTXFSTSx register, to determine if there is enough space in the data FIFO.
  - To write a single nonzero length data packet, there must be space to write the entire packet in the data FIFO.
  - To write zero length packet, the application must not look at the FIFO space.
2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG\_HS\_DIEPCTLx register to avoid modifying the contents of the register, except for setting the Endpoint Enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one micro-frame. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- **Setting IN endpoint NAK**

Internal data flow:

1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint's transmit FIFO.
2. Nonisochronous IN tokens receive a NAK handshake reply
  - Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG\_HS\_DIEPINTx in response to the SNAK bit in OTG\_HS\_DIEPCTLx.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG\_HS\_DIEPCTLx.

Application programming sequence:

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
  - SNAK = 1 in OTG\_HS\_DIEPCTLx
2. Wait for assertion of the INEPNE interrupt in OTG\_HS\_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in DIEPMSK.
  - INEPNEM = 0 in DIEPMSK
5. To exit Endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG\_HS\_DIEPCTLx. This also clears the INEPNE interrupt (in OTG\_HS\_DIEPINTx).
  - CNAK = 1 in OTG\_HS\_DIEPCTLx
6. If the application masked this interrupt earlier, it must be unmasked as follows:
  - INEPNEM = 1 in DIEPMSK

- **IN endpoint disable**

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:

1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
  - SNAK = 1 in OTG\_HS\_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG\_HS\_DIEPINTx.
4. Set the following bits in the OTG\_HS\_DIEPCTLx register for the endpoint that must be disabled.
  - EPDIS = 1 in OTG\_HS\_DIEPCTLx
  - SNAK = 1 in OTG\_HS\_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG\_HS\_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
  - EPENA = 0 in OTG\_HS\_DIEPCTLx
  - EPDIS = 0 in OTG\_HS\_DIEPCTLx
6. The application must read the OTG\_HS\_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the Endpoint transmit FIFO, by setting the following fields in the OTG\_HS\_GRSTCTL register:
  - TXFNUM (in OTG\_HS\_GRSTCTL) = Endpoint transmit FIFO number
  - TXFFLSH in (OTG\_HS\_GRSTCTL) = 1

The application must poll the OTG\_HS\_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

- **Transfer Stop Programming for IN endpoints**

The application must use the following programming sequence to stop any transfers (because of an interrupt from the host, typically a reset).

**Sequence of operations:**

1. Disable the IN endpoint by setting:
  - EPDIS = 1 in all OTG\_HS\_DIEPCTLx registers
2. Wait for the EPDIS interrupt in OTG\_HS\_DIEPINTx, which indicates that the IN endpoint is completely disabled. When the EPDIS interrupt is asserted the following bits are cleared:
  - EPDIS = 0 in OTG\_HS\_DIEPCTLx
  - EPENA = 0 in OTG\_HS\_DIEPCTLx
3. Flush the Tx FIFO by programming the following bits:
  - TXFFLSH = 1 in OTG\_HS\_GRSTCTL
  - TXFNUM = “FIFO number specific to endpoint” in OTG\_HS\_GRSTCTL
4. The application can start polling till TXFFLSH in OTG\_HS\_GRSTCTL is cleared. When this bit is cleared, it ensures that there is no data left in the Tx FIFO.

- **Generic non-periodic IN data transfers**

## Application requirements:

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
  - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 
$$\text{Transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$$
 If ( $\text{sp} > 0$ ), then  $\text{packet count}[\text{EPNUM}] = x + 1$ .  
 Otherwise,  $\text{packet count}[\text{EPNUM}] = x$
  - To transmit a single zero-length data packet:
 
$$\text{Transfer size}[\text{EPNUM}] = 0$$

$$\text{Packet count}[\text{EPNUM}] = 1$$
  - To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
 
$$\text{First transfer: transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{epnum}]; \text{ packet count} = n;$$

$$\text{Second transfer: transfer size}[\text{EPNUM}] = 0; \text{ packet count} = 1;$$
3. Once an endpoint is enabled for data transfers, the core updates the Transfer size register. At the end of the IN transfer, the application must read the Transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.
4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
  - Data transmitted on USB = (application-programmed initial packet count – Core updated final packet count)  $\times$  MPSIZ[EPNUM]
  - Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

## Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every nonisochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when TxFIFO is empty” (ITTXFE) Interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for nonisochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:

1. Program the OTG\_HS\_DIEPTSIz register with the transfer size and corresponding packet count.
2. Program the OTG\_HS\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (Endpoint Enable) bits.
3. When transmitting nonzero length data packet, the application must poll the OTG\_HS\_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG\_HS\_DIEPINTx) before writing the data.

- **Generic periodic IN data transfers**

This section describes a typical periodic IN data transfer.

Application requirements:

1. Application requirements 1, 2, 3, and 4 of [Generic non-periodic IN data transfers on page 1534](#) also apply to periodic IN data transfers, except for a slight modification of requirement 2.
  - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To

transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:

$\text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$

(where  $x$  is an integer  $\geq 0$ , and  $0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]$ )

If ( $\text{sp} > 0$ ),  $\text{packet count}[\text{EPNUM}] = x + 1$

Otherwise,  $\text{packet count}[\text{EPNUM}] = x$ ;

$\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]$

- The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:
  - $\text{transfer size}[\text{EPNUM}] = 0$
  - $\text{packet count}[\text{EPNUM}] = 1$
  - $\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]$
- 2. The application can only schedule data transfers one frame at a time.
  - $(\text{MCNT} - 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}$
  - $\text{PKTCNT} = \text{MCNT}$  (in OTG\_HS\_DIEPTSIZE<sub>x</sub>)
  - If  $\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}$ , the last data packet of the transfer is a short packet.
  - Note that: MCNT is in OTG\_HS\_DIEPTSIZE<sub>x</sub>, MPSIZ is in OTG\_HS\_DIEPCTL<sub>x</sub>, PKTCNT is in OTG\_HS\_DIEPTSIZE<sub>x</sub> and XFERSIZ is in OTG\_HS\_DIEPTSIZE<sub>x</sub>
- 3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:
  - A zero data length packet would be transmitted on the USB for isochronous IN endpoints
  - A NAK handshake would be transmitted on the USB for interrupt IN endpoints
- 4. For a high-bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be  $2 \times \text{max\_pkt\_size}$  and have the third packet loaded in after the first packet has been transmitted on the USB.

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the associated transmit FIFO for the endpoint.
3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO

mode) for the frame is not present in the FIFO, then the core generates an IN token received when TxFIFO empty interrupt for the endpoint.

- A zero-length data packet is transmitted on the USB for isochronous IN endpoints
  - A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. The packet count for the endpoint is decremented by 1 under the following conditions:
    - For isochronous endpoints, when a zero- or nonzero-length data packet is transmitted
    - For interrupt endpoints, when an ACK handshake is transmitted
    - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.
  6. At the “Periodic frame Interval” (controlled by PFIVL in OTG\_HS\_DCFG), when the core finds nonempty any of the isochronous IN endpoint FIFOs scheduled for the current frame nonempty, the core generates an IISOIXFR interrupt in OTG\_HS\_GINTSTS.

Application programming sequence:

1. Program the OTG\_HS\_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG\_HS\_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG\_HS\_DIEPINTx) with no ITTXFE interrupt in OTG\_HS\_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG\_HS\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG\_HS\_DIEPINTx), with or without the ITTXFE interrupt (in OTG\_HS\_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG\_HS\_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG\_HS\_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

#### • Incomplete isochronous IN data transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal data flow:

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
  - a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_HS\_GINTSTS).
  - b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when TxFIFO empty interrupt in OTG\_HS\_DIEPINTx. The application can ignore this interrupt,

as it eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG\_HS\_GINTSTS) at the end of periodic frame.

The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.
3. The application must set the NAK bit and the disable bit for the endpoint.
4. The core disables the endpoint, clears the disable bit, and asserts the Endpoint Disable interrupt for the endpoint.

#### Application programming sequence

1. The application can ignore the IN token received when TxFIFO empty interrupt in OTG\_HS\_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG\_HS\_GINTSTS).
2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG\_HS\_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
3. The application must read the Endpoint Control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
5. Program the following fields in the OTG\_HS\_DIEPCTLx register to disable the endpoint:
  - SNAK = 1 in OTG\_HS\_DIEPCTLx
  - EPDIS = 1 in OTG\_HS\_DIEPCTLx
6. The assertion of the Endpoint Disabled interrupt in OTG\_HS\_DIEPINTx indicates that the core has disabled the endpoint.
  - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next micro-frame. To flush the data, the application must use the OTG\_HS\_GRSTCTL register.

- **Stalling nonisochronous IN endpoints**

This section describes how the application can stall a nonisochronous endpoint.

Application programming sequence:

1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG\_HS\_DIEPCTLx, when the endpoint is already enabled
  - STALL = 1 in OTG\_HS\_DIEPCTLx
  - The STALL bit always takes precedence over the NAK bit
3. Assertion of the Endpoint Disabled interrupt (in OTG\_HS\_DIEPINTx) indicates to the application that the core has disabled the specified endpoint.
4. The application must flush the nonperiodic or periodic transmit FIFO, depending on the endpoint type. In case of a nonperiodic endpoint, the application must re-enable the other nonperiodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the STALL bit must be cleared in OTG\_HS\_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

Special case: stalling the control OUT endpoint

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable the ITTXFE interrupt in OTG\_HS\_DIEPINTx and the OTEPDIS interrupt in OTG\_HS\_DOEPINTx during the data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

### 35.13.8 Worst case response time

When the OTG\_HS controller acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token could come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were dropped.

#### Choosing the value of TRDT in OTG\_HS\_GUSBCFG

The value in TRDT (OTG\_HS\_GUSBCFG) is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from the PFC block. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks.

Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG\_HS\_GUSBCFG).

[Figure 429](#) has the following signals:

- `tkn_rcvd`: Token received information from MAC to PFC
- `dynced_tkn_rcvd`: Doubled sync `tkn_rcvd`, from PCLK to HCLK domain
- `spr_read`: Read to SPRAM
- `spr_addr`: Address to SPRAM
- `spr_rdata`: Read data from SPRAM
- `srcbuf_push`: Push to the source buffer
- `srcbuf_rdata`: Read data from the source buffer. Data seen by MAC

Refer to [Table 214: TRDT values](#) for the values of TRDT versus AHB clock frequency.

**Figure 429. TRDT max timing case**

### 35.13.9 OTG programming model

The OTG\_HS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG\_HS controller turns off  $V_{BUS}$  to conserve power. SRP is a method by which the B-device signals the A-device to turn on  $V_{BUS}$  power. A device must perform both data-line pulsing and  $V_{BUS}$  pulsing, but a host can detect either data-line pulsing or  $V_{BUS}$  pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

#### A-device session request protocol

The application must set the SRP-capable bit in the Core USB configuration register. This enables the OTG\_HS controller to detect SRP as an A-device.

Figure 430. A-device SRP

1. DRV\_VBUS =  $V_{BUS}$  drive signal to the PHY  
 VBUS\_VALID =  $V_{BUS}$  valid signal from PHY  
 A\_VALID = A-device  $V_{BUS}$  level signal to PHY  
 DP = Data plus line  
 DM = Data minus line

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS\_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when V<sub>BUS</sub> power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG\_HS controller detects data-line pulsing.
5. The device drives V<sub>BUS</sub> above the A-device session valid (2.0 V minimum) for V<sub>BUS</sub> pulsing.  
The OTG\_HS controller interrupts the application on detecting SRP. The Session request detected bit is set in Global interrupt status register (SRQINT set in OTG\_HS\_GINTSTS).
6. The application must service the Session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS\_VALID signal.
7. When the USB is powered, the device connects, completing the SRP process.

### B-device session request protocol

The application must set the SRP-capable bit in the Core USB configuration register. This enables the OTG\_HS controller to initiate SRP as a B-device. SRP is a means by which the OTG\_HS controller can request a new session from the host.

Figure 431. B-device SRP

1. VBUS\_VALID = V<sub>BUS</sub> valid signal from PHY  
B\_VALID = B-device valid session to PHY  
DISCHRG\_VBUS = discharge signal to PHY  
SESS\_END = session end signal to PHY  
CHRG\_VBUS = charge V<sub>BUS</sub> signal to PHY  
DP = Data plus line  
DM = Data minus line

1. To save power, the host suspends and turns off port power when the bus is idle.  
The OTG\_HS controller sets the early suspend bit in the Core interrupt register after 3 ms of bus idleness. Following this, the OTG\_HS controller sets the USB suspend bit in the Core interrupt register.  
The OTG\_HS controller informs the PHY to discharge  $V_{BUS}$ .
2. The PHY indicates the session's end to the device. This is the initial condition for SRP.  
The OTG\_HS controller requires 2 ms of SE0 before initiating SRP.  
For a USB 1.1 full-speed serial transceiver, the application must wait until  $V_{BUS}$  discharges to 0.2 V after BSVLD (in OTG\_HS\_GOTGCTL) is deasserted. This discharge time can be obtained from the transceiver vendor and varies from one transceiver to another.
3. The USB OTG core informs the PHY to speed up  $V_{BUS}$  discharge.
4. The application initiates SRP by writing the session request bit in the OTG Control and status register. The OTG\_HS controller perform data-line pulsing followed by  $V_{BUS}$  pulsing.
5. The host detects SRP from either the data-line or  $V_{BUS}$  pulsing, and turns on  $V_{BUS}$ .  
The PHY indicates  $V_{BUS}$  power-on to the device.
6. The OTG\_HS controller performs  $V_{BUS}$  pulsing.  
The host starts a new session by turning on  $V_{BUS}$ , indicating SRP success. The OTG\_HS controller interrupts the application by setting the session request success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.
7. When the USB is powered, the OTG\_HS controller connects, completing the SRP process.

### A-device host negotiation protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the Core USB configuration register to enable the OTG\_HS controller to perform HNP as an A-device.

**Figure 432. A-device HNP**

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

1. The OTG\_HS controller sends the B-device a SetFeature b\_hnp\_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP Enable bit in the OTG Control and status register to indicate to the OTG\_HS controller that the B-device supports HNP.
2. When it has finished using the bus, the application suspends by writing the Port suspend bit in the host port control and status register.
3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The OTG\_HS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.

The OTG\_HS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG\_HS\_DP pull-up resistor to indicate a connect for B-device.

The application must read the current mode bit in the OTG Control and status register to determine peripheral mode operation.
4. The B-device detects the connection, issues a USB reset, and enumerates the OTG\_HS controller for data traffic.
5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The OTG\_HS controller sets the early suspend bit in the Core interrupt register after 3 ms of bus idleness. Following this, the OTG\_HS controller sets the USB Suspend bit in the Core interrupt register.
6. In Negotiated mode, the OTG\_HS controller detects the suspend, disconnects, and switches back to the host role. The OTG\_HS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.
7. The OTG\_HS controller sets the Connector ID status change interrupt in the OTG Interrupt Status register. The application must read the connector ID status in the OTG Control and Status register to determine the OTG\_HS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.
8. The B-device connects, completing the HNP process.

### B-device host negotiation protocol

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the Core USB configuration register to enable the OTG\_HS controller to perform HNP as a B-device.

Figure 433. B-device HNP

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.
1. The A-device sends the SetFeature b\_hnp\_enable descriptor to enable HNP support. The OTG\_HS controller's ACK response indicates that it supports HNP. The application must set the Device HNP enable bit in the OTG Control and status register to indicate HNP support.  
The application sets the HNP request bit in the OTG Control and status register to indicate to the OTG\_HS controller to initiate HNP.
2. When it has finished using the bus, the A-device suspends by writing the Port suspend bit in the host port control and status register.  
The OTG\_HS controller sets the Early suspend bit in the Core interrupt register after 3 ms of bus idleness. Following this, the OTG\_HS controller sets the USB suspend bit in the Core interrupt register.  
The OTG\_HS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG\_HS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.  
The A-device responds by activating its OTG\_HS\_DP pull-up resistor within 3 ms of detecting SE0. The OTG\_HS controller detects this as a connect.  
The OTG\_HS controller sets the host negotiation success status change interrupt in the OTG Interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG Control and status register to determine

host negotiation success. The application must read the current Mode bit in the Core interrupt register (OTG\_HS\_GINTSTS) to determine host mode operation.

3. The application sets the reset bit (PRST in OTG\_HS\_HPRT) and the OTG\_HS controller issues a USB reset and enumerates the A-device for data traffic.
4. The OTG\_HS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the Port suspend bit in the host port control and status register.
5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG\_HS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.
6. The application must read the current mode bit in the Core interrupt (OTG\_HS\_GINTSTS) register to determine the host mode operation.
7. The OTG\_HS controller connects, completing the HNP process.

## 36 Flexible static memory controller (FSMC)

This section applies to the whole STM32F40x/41x family only.

### 36.1 FSMC main features

The FSMC block is able to interface with synchronous and asynchronous memories and 16-bit PC memory cards. Its main purpose is to:

- Translate the AHB transactions into the appropriate external device protocol
- Meet the access timing requirements of the external devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FSMC performs only one access at a time to an external device.

The FSMC has the following main features:

- Interfaces with static memory-mapped devices including:
  - Static random access memory (SRAM)
  - NOR/OneNAND flash memory
  - PSRAM (4 memory banks)
- Two banks of NAND Flash with ECC hardware that checks up to 8 Kbytes of data
- 16-bit PC Card compatible devices
- Supports burst mode access to synchronous devices (NOR flash and PSRAM)
- 8- or 16-bit wide databus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Programmable timings to support a wide range of devices, in particular:
  - Programmable wait states (up to 15)
  - Programmable bus turnaround cycles (up to 15)
  - Programmable output enable and write enable delays (up to 15)
  - Independent read and write timings and protocol, so as to support the widest variety of memories and timings
- Write enable and byte lane select outputs for use with PSRAM and SRAM devices
- Translation of 32-bit wide AHB transactions into consecutive 16-bit or 8-bit accesses to external 16-bit or 8-bit devices
- A Write FIFO, 2-word long (16-word long for STM32F42x and STM32F43x), each word is 32 bits wide, only stores data and not the address. Therefore, this FIFO only buffers AHB write burst transactions. This makes it possible to write to slow memories and free the AHB quickly for other operations. Only one burst at a time is buffered: if a new AHB burst or single transaction occurs while an operation is in progress, the FIFO is drained. The FSMC inserts wait states until the current memory access is complete.
- External asynchronous wait control

The FSMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up. However, it is possible to change the settings at any time.

## 36.2 Block diagram

The FSMC consists of four main blocks:

- The AHB interface (including the FSMC configuration registers)
- The NOR flash/PSRAM controller
- The NAND Flash/PC Card controller
- The external device interface

The block diagram is shown in [Figure 434](#).

**Figure 434. FSMC block diagram**

## 36.3 AHB interface

The AHB slave interface enables internal CPUs and other bus master peripherals to access the external static memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16 or 8 bits wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FSMC Chip Select (FSMC\_NEx) does not

toggle between consecutive accesses except when performing accesses in mode D with the extended mode enabled.

The FSMC generates an AHB error in the following conditions:

- When reading or writing to an FSMC bank which is not enabled
- When reading or writing to the NOR flash bank while the FACCEN bit is reset in the FSMC\_BCRx register.
- When reading or writing to the PC Card banks while the input pin FSMC\_CD (Card Presence Detection) is low.

The effect of this AHB error depends on the AHB master which has attempted the R/W access:

- If it is the Cortex<sup>®</sup>-M4 with FPU CPU, a hard fault interrupt is generated
- If is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FSMC.

### 36.3.1 Supported memories and transactions

#### General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal  
There is no issue in this case.
- AHB transaction size is greater than the memory size  
In this case, the FSMC splits the AHB transaction into smaller consecutive memory accesses in order to meet the external data width.
- AHB transaction size is smaller than the memory size  
Asynchronous transfers may or not be consistent depending on the type of external device.
  - Asynchronous accesses to devices that have the byte select feature (SRAM, ROM, PSRAM).
    - a) FSMC allows write transactions accessing the right data through its byte lanes NBL[1:0]
    - b) Read transactions are allowed. All memory bytes are read and the useless ones are discarded. The NBL[1:0] are kept low during read transactions.
  - Asynchronous accesses to devices that do not have the byte select feature (NOR and NAND Flash 16-bit).  
This situation occurs when a byte access is requested to a 16-bit wide flash memory. Clearly, the device cannot be accessed in byte mode (only 16-bit words can be read from/written to the flash memory) therefore:
    - a) Write transactions are not allowed
    - b) Read transactions are allowed. All memory bytes are read and the useless ones are discarded. The NBL[1:0] are set to 0 during read transactions.

Configuration registers

The FSMC can be configured using a register set. See [Section 36.5.6](#), for a detailed description of the NOR flash/PSRAM control registers. See [Section 36.6.8](#), for a detailed description of the NAND Flash/PC Card registers.

36.4 External device address mapping

From the FSMC point of view, the external memory is divided into 4 fixed-size banks of 256 Mbytes each (Refer to [Figure 435](#)):

- Bank 1 used to address up to four NOR flash or PSRAM memory devices. This bank is split into 4 NOR/PSRAM subbanks with four dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Banks 2 and 3 used to address NAND Flash devices (1 device per bank)
- Bank 4 used to address a PC Card device

For each bank the type of memory to be used is user-defined in the Configuration register.

Figure 435. FSMC memory banks

36.4.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in [Table 217](#).

Table 217. NOR/PSRAM bank selection

| HADDR[27:26] <sup>(1)</sup> | Selected bank        |
|-----------------------------|----------------------|
| 00                          | Bank 1 - NOR/PSRAM 1 |
| 01                          | Bank 1 - NOR/PSRAM 2 |
| 10                          | Bank 1 - NOR/PSRAM 3 |
| 11                          | Bank 1 - NOR/PSRAM 4 |

1. HADDR are internal AHB address lines that are translated to external memory.

HADDR[25:0] contain the external memory address. Since HADDR is a byte address whereas the memory is addressed in words, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 218. External memory address

| Memory width <sup>(1)</sup> | Data address issued to the memory | Maximum memory capacity (bits) |
|-----------------------------|-----------------------------------|--------------------------------|
| 8-bit                       | HADDR[25:0]                       | 64 Mbyte x 8 = 512 Mbit        |
| 16-bit                      | HADDR[25:1] >> 1                  | 64 Mbyte/2 x 16 = 512 Mbit     |

1. In case of a 16-bit external memory width, the FSMC internally uses HADDR[25:1] to generate the address for external memory FSMC\_A[24:0].  
Whatever the external memory width (16-bit or 8-bit), FSMC\_A[0] should be connected to external memory address A[0].

### Wrap support for NOR flash/PSRAM

Wrap burst mode for synchronous memories is not supported. The memories must be configured in linear burst mode of undefined length.

## 36.4.2 NAND/PC Card address mapping

In this case, three banks are available, each of them divided into memory spaces as indicated in [Table 219](#).

Table 219. Memory mapping and timing registers

| Start address | End address | FSMC Bank           | Memory space | Timing register   |
|---------------|-------------|---------------------|--------------|-------------------|
| 0x9C00 0000   | 0x9FFF FFFF | Bank 4 - PC card    | I/O          | FSMC_PIO4 (0xB0)  |
| 0x9800 0000   | 0x9BFF FFFF |                     | Attribute    | FSMC_PATT4 (0xAC) |
| 0x9000 0000   | 0x93FF FFFF |                     | Common       | FSMC_PMEM4 (0xA8) |
| 0x8800 0000   | 0x8BFF FFFF | Bank 3 - NAND Flash | Attribute    | FSMC_PATT3 (0x8C) |
| 0x8000 0000   | 0x83FF FFFF |                     | Common       | FSMC_PMEM3 (0x88) |
| 0x7800 0000   | 0x7BFF FFFF | Bank 2- NAND Flash  | Attribute    | FSMC_PATT2 (0x6C) |
| 0x7000 0000   | 0x73FF FFFF |                     | Common       | FSMC_PMEM2 (0x68) |

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in [Table 220](#) below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

**Table 220. NAND bank selections**

| Section name    | HADDR[17:16] | Address range     |
|-----------------|--------------|-------------------|
| Address section | 1X           | 0x020000-0x03FFFF |
| Command section | 01           | 0x010000-0x01FFFF |
| Data section    | 00           | 0x000000-0x0FFFFF |

The application software uses the 3 sections to access the NAND Flash memory:

- **To send a command to NAND Flash memory:** the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written:** the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive writes to the address section are needed to specify the full address.
- **To read or write data:** the software reads or writes the data value from or to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

## 36.5 NOR flash/PSRAM controller

The FSMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8-bit
  - 16-bit
  - 32-bit
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or nonmultiplexed
- NOR flash
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or nonmultiplexed

The FSMC outputs a unique chip select signal NE[4:1] per bank. All the other signals (addresses, data and control) are shared.

For synchronous accesses, the FSMC issues the clock (CLK) to the selected external device only during the read/write transactions. This clock is a submultiple of the HCLK clock. The size of each bank is fixed and equal to 64 Mbytes.

Each bank is configured by means of dedicated registers (see [Section 36.5.6](#)).

The programmable memory parameters include access timings (see [Table 221](#)) and support for wait management (for PSRAM and NOR flash accessed in burst mode).

**Table 221. Programmable NOR/PSRAM access parameters**

| Parameter          | Function                                                                         | Access mode                             | Unit                     | Min. | Max. |
|--------------------|----------------------------------------------------------------------------------|-----------------------------------------|--------------------------|------|------|
| Address setup      | Duration of the address setup phase                                              | Asynchronous                            | AHB clock cycle (HCLK)   | 0    | 15   |
| Address hold       | Duration of the address hold phase                                               | Asynchronous, muxed I/Os                | AHB clock cycle (HCLK)   | 1    | 15   |
| Data setup         | Duration of the data setup phase                                                 | Asynchronous                            | AHB clock cycle (HCLK)   | 1    | 256  |
| Bus turn           | Duration of the bus turnaround phase                                             | Asynchronous and synchronous read/write | AHB clock cycle (HCLK)   | 0    | 15   |
| Clock divide ratio | Number of AHB clock cycles (HCLK) to build one memory clock cycle (CLK)          | Synchronous                             | AHB clock cycle (HCLK)   | 2    | 16   |
| Data latency       | Number of clock cycles to issue to the memory before the first data of the burst | Synchronous                             | Memory clock cycle (CLK) | 2    | 17   |

### 36.5.1 External memory interface signals

[Table 222](#), [Table 223](#) and [Table 224](#) list the signals that are typically used to interface NOR flash, SRAM and PSRAM.

*Note:* Prefix “N”. specifies the associated signal as active low.

#### NOR flash, nonmultiplexed I/Os

**Table 222. Nonmultiplexed I/O NOR flash**

| FSMC signal name | I/O | Function                                                                            |
|------------------|-----|-------------------------------------------------------------------------------------|
| CLK              | O   | Clock (for synchronous access)                                                      |
| A[25:0]          | O   | Address bus                                                                         |
| D[15:0]          | I/O | Bidirectional data bus                                                              |
| NE[x]            | O   | Chip select, x = 1..4                                                               |
| NOE              | O   | Output enable                                                                       |
| NWE              | O   | Write enable                                                                        |
| NL(=NADV)        | O   | Latch enable (this signal is called address valid, NADV, by some NOR flash devices) |
| NWAIT            | I   | NOR flash wait input signal to the FSMC                                             |

NOR flash memories are addressed in 16-bit words. The maximum capacity is 512 Mbit (26 address lines).

### NOR flash, multiplexed I/Os

**Table 223. Multiplexed I/O NOR flash**

| FSMC signal name | I/O | Function                                                                            |
|------------------|-----|-------------------------------------------------------------------------------------|
| CLK              | O   | Clock (for synchronous access)                                                      |
| A[25:16]         | O   | Address bus                                                                         |
| AD[15:0]         | I/O | 16-bit multiplexed, bidirectional address/data bus                                  |
| NE[x]            | O   | Chip select, x = 1..4                                                               |
| NOE              | O   | Output enable                                                                       |
| NWE              | O   | Write enable                                                                        |
| NL(=NADV)        | O   | Latch enable (this signal is called address valid, NADV, by some NOR flash devices) |
| NWAIT            | I   | NOR flash wait input signal to the FSMC                                             |

NOR-flash memories are addressed in 16-bit words. The maximum capacity is 512 Mbit (26 address lines).

### PSRAM/SRAM, nonmultiplexed I/Os

**Table 224. Nonmultiplexed I/Os PSRAM/SRAM**

| FSMC signal name | I/O | Function                                                             |
|------------------|-----|----------------------------------------------------------------------|
| CLK              | O   | Clock (only for PSRAM synchronous access)                            |
| A[25:0]          | O   | Address bus                                                          |
| D[15:0]          | I/O | Data bidirectional bus                                               |
| NE[x]            | O   | Chip select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM)) |
| NOE              | O   | Output enable                                                        |
| NWE              | O   | Write enable                                                         |
| NL(= NADV)       | O   | Address valid only for PSRAM input (memory signal name: NADV)        |
| NWAIT            | I   | PSRAM wait input signal to the FSMC                                  |
| NBL[1]           | O   | Upper byte enable (memory signal name: NUB)                          |
| NBL[0]           | O   | Lower byte enable (memory signal name: NLB)                          |

PSRAM memories are addressed in 16-bit words. The maximum capacity is 512 Mbit (26 address lines).

PSRAM, multiplexed I/Os

Table 225. Multiplexed I/O PSRAM

| FSMC signal name | I/O | Function                                                             |
|------------------|-----|----------------------------------------------------------------------|
| CLK              | O   | Clock (for synchronous access)                                       |
| A[25:16]         | O   | Address bus                                                          |
| AD[15:0]         | I/O | 16-bit multiplexed, bidirectional address/data bus                   |
| NE[x]            | O   | Chip select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM)) |
| NOE              | O   | Output enable                                                        |
| NWE              | O   | Write enable                                                         |
| NL(= NADV)       | O   | Address valid PSRAM input (memory signal name: NADV)                 |
| NWAIT            | I   | PSRAM wait input signal to the FSMC                                  |
| NBL[1]           | O   | Upper byte enable (memory signal name: NUB)                          |
| NBL[0]           | O   | Lower byte enable (memory signal name: NLB)                          |

PSRAM memories are addressed in 16-bit words. The maximum capacity is 512 Mbit (26 address lines).

### 36.5.2 Supported memories and transactions

[Table 226](#) below displays an example of the supported devices, access modes and transactions when the memory data bus is 16-bit for NOR, PSRAM and SRAM. Transactions not allowed (or not supported) by the FSMC in this example appear in gray.

Table 226. NOR flash/PSRAM controller: example of supported memories and transactions

| Device                                      | Mode              | R/W | AHB data size | Memory data size | Allowed/ not allowed | Comments                     |
|---------------------------------------------|-------------------|-----|---------------|------------------|----------------------|------------------------------|
| NOR flash<br>(muxed I/Os and nonmuxed I/Os) | Asynchronous      | R   | 8             | 16               | Y                    | -                            |
|                                             | Asynchronous      | W   | 8             | 16               | N                    | -                            |
|                                             | Asynchronous      | R   | 16            | 16               | Y                    | -                            |
|                                             | Asynchronous      | W   | 16            | 16               | Y                    | -                            |
|                                             | Asynchronous      | R   | 32            | 16               | Y                    | Split into two FSMC accesses |
|                                             | Asynchronous      | W   | 32            | 16               | Y                    | Split into two FSMC accesses |
|                                             | Asynchronous page | R   | -             | 16               | N                    | Mode is not supported        |
|                                             | Synchronous       | R   | 8             | 16               | N                    | -                            |
|                                             | Synchronous       | R   | 16            | 16               | Y                    | -                            |
|                                             | Synchronous       | R   | 32            | 16               | Y                    | -                            |

Table 226. NOR flash/PSRAM controller: example of supported memories and transactions

| Device                                      | Mode              | R/W | AHB data size | Memory data size | Allowed/ not allowed | Comments                                                 |
|---------------------------------------------|-------------------|-----|---------------|------------------|----------------------|----------------------------------------------------------|
| PSRAM (multiplexed and nonmultiplexed I/Os) | Asynchronous      | R   | 8             | 16               | Y                    | -                                                        |

|                                             | Synchronous       | W   | 8             | 16               | Y                    | Use of byte lanes NBL[1:0]                               |
|                                             | Synchronous       | W   | 16 / 32       | 16               | Y                    | -                                                        |
| SRAM and ROM                                | Asynchronous      | R   | 8 / 16        | 16               | Y                    | -                                                        |
|                                             | Asynchronous      | W   | 8 / 16        | 16               | Y                    | Use of byte lanes NBL[1:0]                               |
|                                             | Asynchronous      | R   | 32            | 16               | Y                    | Split into two FSMC accesses                             |
|                                             | Asynchronous      | W   | 32            | 16               | Y                    | Split into two FSMC accesses. Use of byte lanes NBL[1:0] |

### 36.5.3 General timing rules

#### Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADV L/ NADV H/ NBLL/ Address valid outputs change on the falling edge of FSMC\_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FSMC\_CLK clock.

### 36.5.4 NOR flash/PSRAM controller asynchronous transactions

#### Asynchronous static memories (NOR flash memory, PSRAM, SRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory
- The FSMC always samples the data before de-asserting the NOE signals. This guarantees that the memory data-hold timing constraint is met (chip enable high to data transition, usually 0 ns min.)
- If the extended mode is enabled (EXTMOD bit is set in the FSMC\_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the extended mode is disabled (EXTMOD bit is reset in the FSMC\_BCRx register), the FSMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP[0:1] = 0x0 or 0x01 in the FSMC\_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP[0:1] = 0x10 in the FSMC\_BCRx register).

#### Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FSMC\_BCRx, and FSMC\_BTRx/FSMC\_BWTRx registers.

**Figure 436. Mode1 read accesses**

1. NBL[1:0] are driven low during read access.

Figure 437. Mode1 write accesses

ai15558

The one HCLK cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this one HCLK cycle, the DATAST value must be greater than zero ( $\text{DATAST} > 0$ ).

Table 227. FSMC\_BCRx bit fields

| Bit number | Bit name  | Value to set                                                       |
|------------|-----------|--------------------------------------------------------------------|
| 31-20      | Reserved  | 0x000                                                              |
| 19         | CBURSTRW  | 0x0 (no effect on asynchronous mode)                               |
| 18:16      | CPSIZE    | 0x0 (no effect on asynchronous mode)                               |
| 15         | ASYNCWAIT | Set to 1 if the memory supports this feature. Otherwise keep at 0. |
| 14         | EXTMOD    | 0x0                                                                |
| 13         | WAITEN    | 0x0 (no effect on asynchronous mode)                               |
| 12         | WREN      | As needed                                                          |
| 11         | WAITCFG   | Don't care                                                         |
| 10         | WRAPMOD   | 0x0                                                                |
| 9          | WAITPOL   | Meaningful only if bit 15 is 1                                     |
| 8          | BURSTEN   | 0x0                                                                |
| 7          | Reserved  | 0x1                                                                |
| 6          | FACCEN    | Don't care                                                         |
| 5-4        | MWID      | As needed                                                          |
| 3-2        | MTYP[0:1] | As needed, exclude 0x2 (NOR flash)                                 |

Table 227. FSMC\_BCRx bit fields (continued)

| Bit number | Bit name | Value to set |
|------------|----------|--------------|
| 1          | MUXE     | 0x0          |
| 0          | MBKEN    | 0x1          |

Table 228. FSMC\_BTRx bit fields

| Bit number | Bit name    | Value to set                                                                                                         |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------|
| 31:30      | Reserved    | 0x0                                                                                                                  |
| 29-28      | ACCMOD      | Don't care                                                                                                           |
| 27-24      | DATLAT      | Don't care                                                                                                           |
| 23-20      | CLKDIV      | Don't care                                                                                                           |
| 19-16      | BUSTURN     | Time between NEx high to NEx low (BUSTURN HCLK)                                                                      |
| 15-8       | DATAST      | Duration of the second access phase (DATAST+1 HCLK cycles for write accesses, DATAST HCLK cycles for read accesses). |

| 3-0        | ADDSET[3:0] | Duration of the first access phase (ADDSET HCLK cycles).<br>Minimum value for ADDSET is 0.                           |

### Mode A - SRAM/PSRAM (CRAM) OE toggling

Figure 438. ModeA read accesses

ai15559

1. NBL[1:0] are driven low during read access.

Figure 439. ModeA write accesses

The differences compared with mode1 are the toggling of NOE and the independent read and write timings.

Table 229. FSMC\_BCRx bit fields

| Bit number | Bit name  | Value to set                                                       |
|------------|-----------|--------------------------------------------------------------------|
| 31-20      | Reserved  | 0x000                                                              |
| 19         | CBURSTRW  | 0x0 (no effect on asynchronous mode)                               |
| 18:16      | CPSIZE    | 0x0 (no effect on asynchronous mode)                               |
| 15         | ASYNCWAIT | Set to 1 if the memory supports this feature. Otherwise keep at 0. |
| 14         | EXTMOD    | 0x1                                                                |

**Mode D - asynchronous access with extended address**

Figure 445. Mode D read accesses

Figure 446. Mode D write accesses

The differences with mode1 are the toggling of NOE that goes on toggling after NADV changes and the independent read and write timings.

Table 238. FSMC\_BCRx bit fields

| Bit No. | Bit name  | Value to set                                                       |

| 3-0     | ADDSET[3:0] | Duration of the first access phase (ADDSET HCLK cycles).<br>Minimum value for ADDSET is 1.                              |

### WAIT management in asynchronous accesses

If the asynchronous memory asserts a WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FSMC\_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase) programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET[3:0] and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase (DATAST in the FSMC\_BTRx register) must be programmed so that WAIT can be detected 4 HCLK cycles before the end of memory transaction. The following cases must be considered:

1. DATAST in FSMC\_BTRx register) Memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$\text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time}$$

2. Memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):  
if

$$\text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}$$

then

$$\text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase})$$

otherwise

$$\text{DATAST} \geq 4 \times \text{HCLK}$$

where max\_wait\_assertion\_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

[Figure 449](#) and [Figure 450](#) show the number of HCLK clock cycles that are added to the memory access after WAIT is released by the asynchronous memory (independently of the above cases).

**Figure 449. Asynchronous wait during a read access**

1. NWAIT polarity depends on WAITPOL bit setting in FSMC\_BCRx register.

**Figure 450. Asynchronous wait during a write access**

1. NWAIT polarity depends on WAITPOL bit setting in FSMC\_BCRx register.

### 36.5.5 Synchronous transactions

The memory clock, CLK, is a submultiple of HCLK according to the value of parameter CLKDIV.

NOR flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FSMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs *in the middle* of the NADV low pulse.

#### Data latency versus NOR flash latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration register. The FSMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR flash memories include the NADV Low cycle in the data latency count, so the exact relation between the latency and the FSMC DATLAT parameter can be either of:

- NOR flash latency = (DATLAT + 2) CLK clock cycles
- NOR flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FSMC samples the data and waits long enough to evaluate if the data are valid. Thus the FSMC detects when the memory exits latency and real data are taken.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FSMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

#### Single-burst transfer

When the selected bank is configured in burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FSMC performs a burst transaction of length 1 (if the AHB transfer is 16-bit), or length 2 (if the AHB transfer is 32-bit) and de-assert the chip select signal when the last data is strobed.

Clearly, such a transfer is not the most efficient in terms of cycles (compared to an asynchronous read). Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

#### Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FSMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FSMC\_BCR1 register following the memory page size.

#### Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, (DATLAT+2) CLK clock cycles.

If NWAIT is sensed active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is sensed inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid, and does not consider the data valid.

There are two timing configurations for the NOR flash NWAIT signal in burst mode:

- Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset)
- Flash memory asserts the NWAIT signal during the wait state

These two NOR flash wait state configurations are supported by the FSMC, individually for each chip select, thanks to the WAITCFG bit in the FSMC\_BCRx registers (x = 0..3).

**Figure 451. Wait configurations**

**Figure 452. Synchronous multiplexed read mode - NOR, PSRAM (CRAM)**

1. Byte lane outputs BL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.
2. NWAIT polarity is set to 0.

**Table 243. FSMC\_BCRx bit fields**

| Bit No. | Bit name  | Value to set                                                       |
|---------|-----------|--------------------------------------------------------------------|
| 31-20   | Reserved  | 0x000                                                              |

### 36.5.6 NOR/PSRAM control registers

The NOR/PSRAM control registers have to be accessed by words (32 bits).

#### SRAM/NOR-flash chip-select control registers 1..4 (FSMC\_BCR1..4)

Address offset:  $0xA000\ 0000 + 8 * (x - 1)$ ,  $x = 1...4$

Reset value: 0x0000 30DB for Bank1 and 0x0000 30D2 for Bank 2 to 4

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18          | 17 | 16 | 15        | 14     | 13     | 12   | 11      | 10      | 9       | 8       | 7        | 6      | 5         | 4  | 3         | 2  | 1     | 0     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----------|-------------|----|----|-----------|--------|--------|------|---------|---------|---------|---------|----------|--------|-----------|----|-----------|----|-------|-------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    | CBURSTRW | CPSIZE[2:0] |    |    | ASCYCWAIT | EXTMOD | WAITEN | WREN | WAITCFG | WRAPMOD | WAITPOL | BURSTEN | Reserved | FACCEN | MWID[1:0] |    | MTYP[1:0] |    | MUXEN | MBKEN |
|          |    |    |    |    |    |    |    |    |    |    |    | RW       |             |    |    | RW        | RW     | RW     | RW   | RW      | RW      | RW      | RW      |          |        | RW        | RW | RW        | RW | RW    |       |
|          |    |    |    |    |    |    |    |    |    |    |    |          |             |    |    |           |        |        |      |         |         |         |         |          |        |           |    |           |    |       |       |

Bits 31: 20 Reserved, must be kept at reset value.

Bit 19 **CBURSTRW**: Write burst enable.

For Cellular RAM (PSRAM) memories, this bit enables the synchronous burst protocol during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FSMC\_BCRx register.

0: Write operations are always performed in asynchronous mode

1: Write operations are performed in synchronous mode.

Bits 18: 16 **CPSIZE[2:0]**: CRAM page size.

These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FSMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset)

001: 128 bytes

010: 256 bytes

011: 512 bytes

100: 1024 bytes

Others: reserved.

Bit 15 **ASYNCAWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FSMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken into account when running an asynchronous protocol (default after reset)

1: NWAIT signal is taken into account when running an asynchronous protocol

Bit 14 **EXTMOD**: Extended mode enable.

This bit enables the FSMC to program the write timings for non-multiplexed asynchronous accesses inside the FSMC\_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FSMC\_BWTR register are not taken into account (default after reset)

1: values inside FSMC\_BWTR register are taken into account

*Note: When the extended mode is disabled, the FSMC can operate in Mode1 or Mode2 as follows:*

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP [0:1]=0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP [0:1]= 0x10).*

Bit 13 **WAITEN**: Wait enable bit.

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the flash memory in synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period)

1: NWAIT signal is enabled (its level is taken into account after the programmed flash latency period to insert wait states if asserted) (default after reset)

Bit 12 **WREN**: Write enable bit.

This bit indicates whether write operations are enabled/disabled in the bank by the FSMC:

0: Write operations are disabled in the bank by the FSMC, an AHB error is reported,

1: Write operations are enabled for the bank by the FSMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration.

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the flash memory in synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset),

1: NWAIT signal is active during wait state (not used for PRAM).

Bit 10 **WRAPMOD**: Wrapped burst mode support.

Defines whether the controller splits or not an AHB burst wrap access into two linear accesses. Valid only when accessing memories in burst mode

0: Direct wrapped burst is not enabled (default after reset),

1: Direct wrapped burst is enabled.

*Note: This bit has no effect as the CPU and DMA cannot generate wrapping burst transfers.*

Bit 9 **WAITPOL**: Wait signal polarity bit.

Defines the polarity of the wait signal from memory. Valid only when accessing the memory in burst mode:

0: NWAIT active low (default after reset),

1: NWAIT active high.

Bit 8 **BURSTEN**: Burst enable bit.

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in burst mode:

0: Burst mode disabled (default after reset). Read accesses are performed in asynchronous mode.

1: Burst mode enable. Read accesses are performed in synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

Enables NOR flash memory access operations.

0: Corresponding NOR flash memory access is disabled

1: Corresponding NOR flash memory access is enabled (default after reset)

Bits 5:4 **MWID[1:0]**: Memory databus width.

Defines the external memory device width, valid for all type of memories.

00: 8 bits,

01: 16 bits (default after reset),

10: reserved, do not use,

11: reserved, do not use.

Bits 3:2 **MTYP[1:0]**: Memory type.

Defines the type of external memory attached to the corresponding memory bank:

00: SRAM (default after reset for Bank 2...4)

01: PSRAM (CRAM)

10: NOR flash/OneNAND flash (default after reset for Bank 1)

11: reserved

Bit 1 **MUXEN**: Address/data multiplexing enable bit.

When this bit is set, the address and data values are multiplexed on the databus, valid only with NOR and PSRAM memories:

0: Address/Data nonmultiplexed

1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN**: Memory bank enable bit.

Enables the memory bank. After reset Bank1 is enabled, all others are disabled.

Accessing a disabled bank causes an ERROR on AHB bus.

0: Corresponding memory bank is disabled

1: Corresponding memory bank is enabled

**SRAM/NOR-Flash chip-select timing registers 1..4 (FSMC\_BTR1..4)**

Address offset:  $0xA000\ 0000 + 0x04 + 8 * (x - 1)$ ,  $x = 1..4$

Reset value:  $0x0FFF\ FFFF$

FSMC\_BTRx bits are written by software to add a delay at the end of a read /write transaction. This delay allows matching the minimum time between consecutive transactions ( $t_{EHEL}$  from NEx high to FSMC\_NEx low) and the maximum time required by the memory to free the data bus after a read access ( $t_{EHQZ}$ ).

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories. If the EXTMOD bit is set in the FSMC\_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FSMC\_BWTRx registers).

| 31       | 30 | 29          | 28 | 27          | 26 | 25 | 24 | 23          | 22 | 21 | 20 | 19           | 18 | 17 | 16 | 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8           | 7  | 6  | 5  | 4           | 3  | 2  | 1  | 0 |
|----------|----|-------------|----|-------------|----|----|----|-------------|----|----|----|--------------|----|----|----|-------------|----|----|----|----|----|----|-------------|----|----|----|-------------|----|----|----|---|
| Reserved |    | ACCMOD[1:0] |    | DATLAT[3:0] |    |    |    | CLKDIV[3:0] |    |    |    | BUSTURN[3:0] |    |    |    | DATAST[7:0] |    |    |    |    |    |    | ADDHLD[3:0] |    |    |    | ADDSET[3:0] |    |    |    |   |
|          |    | rW          | rW | rW          | rW | rW | rW | rW          | rW | rW | rW | rW           | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW          | rW | rW | rW |   |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]**: Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FSMC\_BCRx register is 1.

- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:24 **DATLAT[3:0]**: Data latency for synchronous memory (see note below bit description table)

For synchronous accesses with read/write burst mode enabled (BURSTEN / CBURSTRW bits set), this field defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data. This timing parameter is not expressed in HCLK periods, but in FSMC\_CLK periods. For asynchronous accesses, this value is don't care.

- 0000: Data latency of 2 CLK clock cycles for first burst access
- 1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FSMC\_CLK signal)

Defines the period of FSMC\_CLK clock output signal, expressed in number of HCLK cycles:

- 0000: Reserved
- 0001: FSMC\_CLK period =  $2 \times$  HCLK periods
- 0010: FSMC\_CLK period =  $3 \times$  HCLK periods
- 1111: FSMC\_CLK period =  $16 \times$  HCLK periods (default value after reset)

In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don't care.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. The programmed bus turnaround delay is inserted between an asynchronous read (muxed or D mode) or a write transaction and any other asynchronous/synchronous read or write to/from a static bank (for a read operation, the bank can be the same or a different one; for a write operation, the bank can be different except in r muxed or D mode).

In some cases, the bus turnaround delay is fixed, whatever the programmed BUSTURN values:

- No bus turnaround delay is inserted between two consecutive asynchronous write transfers to the same static memory bank except in muxed and D mode.
- A bus turnaround delay of 1 FSMC clock cycle is inserted between:
  - Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - An asynchronous (modes 1, 2, A, B or C) read and a read operation from another static bank.
- A bus turnaround delay of 2 FSMC clock cycles is inserted between:
  - Two consecutive synchronous write accesses (in burst or single mode) to the same bank
  - A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different in case of a read operation).
  - Two consecutive synchronous read accesses (in burst or single mode) followed by a any synchronous/asynchronous read or write from/to another static memory bank.
- A bus turnaround delay of 3 FSMC clock cycles is inserted between:
  - Two consecutive synchronous write operations (in burst or single mode) to different static banks.
  - A synchronous write access (in burst or single mode) and a synchronous read access from the same or to a different bank.

0000: BUSTURN phase duration = 0 HCLK clock cycle added

...

1111: BUSTURN phase duration = 15 × HCLK clock cycles (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration

These bits are written by software to define the duration of the data phase (refer to [Figure 436](#) to [Figure 448](#)), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × HCLK clock cycles

0000 0010: DATAST phase duration = 2 × HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure ([Figure 436](#) to [Figure 448](#)).

Example: Mode1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

*Note: In synchronous accesses, this value is don't care.*

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 445](#) to [Figure 448](#)), used in mode D and multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × HCLK clock cycle

0010: ADDHLD phase duration = 2 × HCLK clock cycle

...

1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address-hold phase duration, refer to the respective figure ([Figure 445](#) to [Figure 448](#)).

*Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.*

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to [Figure 436](#) to [Figure 448](#)), used in SRAMs, ROMs and asynchronous NOR flash and PSRAM accesses:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address setup phase duration, refer to the respective figure (refer to [Figure 436](#) to [Figure 448](#)).

*Note: In synchronous NOR flash and PSRAM accesses, this value is don't care.*

**Note:** *PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.*

*With PSRAMs (CRAMs) the DATLAT field must be set to 0, so that the FSMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.*

*This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).*

**SRAM/NOR-Flash write timing registers 1..4 (FSMC\_BWTR1..4)**

Address offset:  $0xA000\ 0000 + 0x104 + 8 * (x - 1)$ ,  $x = 1...4$

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAMs and NOR flash memories. This register is active for write asynchronous access only when the EXTMOD bit is set in the FSMC\_BCRx register.

|      |                 |    |          |    |    |    |    |    |    |    |    |              |    |    |    |             |    |    |    |    |    |    |    |             |    |    |    |             |    |    |    |
|------|-----------------|----|----------|----|----|----|----|----|----|----|----|--------------|----|----|----|-------------|----|----|----|----|----|----|----|-------------|----|----|----|-------------|----|----|----|
| 31   | 30              | 29 | 28       | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19           | 18 | 17 | 16 | 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3           | 2  | 1  | 0  |
| Res. | ACCM<br>OD[2:0] |    | Reserved |    |    |    |    |    |    |    |    | BUSTURN[3:0] |    |    |    | DATAST[7:0] |    |    |    |    |    |    |    | ADDHLD[3:0] |    |    |    | ADDSET[3:0] |    |    |    |
|      | rW              | rW |          |    |    |    |    |    |    |    |    | rW           | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW          | rW | rW | rW |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[2:0]**: Access mode.

Specifies the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FSMC\_BCRx register is 1.

- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

The programmed bus turnaround delay is inserted between a an asynchronous write transfer and any other asynchronous/synchronous read or write transfer to/from a static bank (for a read operation, the bank can be the same or a different one; for a write operation, the bank can be different except in r muxed or D mode).

In some cases, the bus turnaround delay is fixed, whatever the programmed BUSTURN values:

- No bus turnaround delay is inserted between two consecutive asynchronous write transfers to the same static memory bank except in muxed and D mode.
- A bus turnaround delay of 2 FSMC clock cycles is inserted between:
  - Two consecutive synchronous write accesses (in burst or single mode) to the same bank.
  - A synchronous write transfer (in burst or single mode) and an asynchronous write or read transfer to/from static a memory bank.
- A bus turnaround delay of 3 FSMC clock cycles is inserted between:
  - Two consecutive synchronous write accesses (in burst or single mode) to different static banks.
  - A synchronous write transfer (in burst or single mode) and a synchronous read from the same or from a different bank.

0000: BUSTURN phase duration = 0 HCLK clock cycle added

...

1111: BUSTURN phase duration = 15 HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]**: Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to [Figure 436](#) to [Figure 448](#)), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × HCLK clock cycles

0000 0010: DATAST phase duration = 2 × HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

*Note: In synchronous accesses, this value is don't care.*

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 445](#) to [Figure 448](#)), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × HCLK clock cycle

0010: ADDHLD phase duration = 2 × HCLK clock cycle

...

1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

*Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.*

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in HCLK cycles (refer to [Figure 445](#) to [Figure 448](#)), used in asynchronous accessed:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

*Note: In synchronous NOR flash and PSRAM accesses, this value is don't care.*

## 36.6 NAND Flash/PC Card controller

The FSMC generates the appropriate signal timings to drive the following types of device:

- NAND Flash
  - 8-bit
  - 16-bit
- 16-bit PC Card compatible devices

The NAND/PC Card controller can control three external banks. Bank 2 and bank 3 support NAND Flash devices. Bank 4 supports PC Card devices.

Each bank is configured by means of dedicated registers ([Section 36.6.8](#)). The programmable memory parameters include access timings (shown in [Table 247](#)) and ECC configuration.

Table 247. Programmable NAND/PC Card access parameters

| Parameter             | Function                                                                                                                  | Access mode | Unit                   | Min. | Max. |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|-------------|------------------------|------|------|
| Memory setup time     | Number of clock cycles (HCLK) to set up the address before the command assertion                                          | Read/Write  | AHB clock cycle (HCLK) | 1    | 255  |
| Memory wait           | Minimum duration (HCLK clock cycles) of the command assertion                                                             | Read/Write  | AHB clock cycle (HCLK) | 2    | 256  |
| Memory hold           | Number of clock cycles (HCLK) to hold the address (and the data in case of a write access) after the command de-assertion | Read/Write  | AHB clock cycle (HCLK) | 1    | 254  |
| Memory databus high-Z | Number of clock cycles (HCLK) during which the databus is kept in high-Z state after the start of a write access          | Write       | AHB clock cycle (HCLK) | 0    | 255  |

### 36.6.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND Flash and PC Card.

Note: Prefix "N". specifies the associated signal as active low.

#### 8-bit NAND Flash

Table 248. 8-bit NAND Flash

| FSMC signal name | I/O | Function                                             |
|------------------|-----|------------------------------------------------------|
| A[17]            | O   | NAND Flash address latch enable (ALE) signal         |
| A[16]            | O   | NAND Flash command latch enable (CLE) signal         |
| D[7:0]           | I/O | 8-bit multiplexed, bidirectional address/data bus    |
| NCE[x]           | O   | Chip select, x = 2, 3                                |
| NOE(= NRE)       | O   | Output enable (memory signal name: read enable, NRE) |
| NWE              | O   | Write enable                                         |
| NWAIT/INT[3:2]   | I   | NAND Flash ready/busy input signal to the FSMC       |

There is no theoretical capacity limitation as the FSMC can manage as many address cycles as needed.

**16-bit NAND Flash****Table 249. 16-bit NAND Flash**

| FSMC signal name | I/O | Function                                             |
|------------------|-----|------------------------------------------------------|
| A[17]            | O   | NAND Flash address latch enable (ALE) signal         |
| A[16]            | O   | NAND Flash command latch enable (CLE) signal         |
| D[15:0]          | I/O | 16-bit multiplexed, bidirectional address/data bus   |
| NCE[x]           | O   | Chip select, x = 2, 3                                |
| NOE(= NRE)       | O   | Output enable (memory signal name: read enable, NRE) |
| NWE              | O   | Write enable                                         |
| NWAIT/INT[3:2]   | I   | NAND Flash ready/busy input signal to the FSMC       |

*There is no theoretical capacity limitation as the FSMC can manage as many address cycles as needed.*

**16-bit PC Card****Table 250. 16-bit PC Card**

| FSMC signal name | I/O | Function                                                                                                                                                                                 |
|------------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A[10:0]          | O   | Address bus                                                                                                                                                                              |
| NIORD            | O   | Output enable for I/O space                                                                                                                                                              |
| NIOWR            | O   | Write enable for I/O space                                                                                                                                                               |
| NREG             | O   | Register signal indicating if access is in Common or Attribute space                                                                                                                     |
| D[15:0]          | I/O | Bidirectional databus                                                                                                                                                                    |
| NCE4_1           | O   | Chip select 1                                                                                                                                                                            |
| NCE4_2           | O   | Chip select 2 (indicates if access is 16-bit or 8-bit)                                                                                                                                   |
| NOE              | O   | Output enable in Common and in Attribute space                                                                                                                                           |
| NWE              | O   | Write enable in Common and in Attribute space                                                                                                                                            |
| NWAIT            | I   | PC Card wait input signal to the FSMC (memory signal name IORDY)                                                                                                                         |
| INTR             | I   | PC Card interrupt to the FSMC (only for PC Cards that can generate an interrupt)                                                                                                         |
| CD               | I   | PC Card presence detection. Active high. If an access is performed to the PC Card banks while CD is low, an AHB error is generated. Refer to <a href="#">Section 36.3: AHB interface</a> |

### 36.6.2 NAND Flash / PC Card supported memories and transactions

*Table 251 below shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND Flash / PC Card controller appear in gray.*

**Table 251. Supported memories and transactions**

| Device      | Mode         | R/W | AHB data size | Memory data size | Allowed/not allowed | Comments                   |
|-------------|--------------|-----|---------------|------------------|---------------------|----------------------------|
| NAND 8-bit  | Asynchronous | R   | 8             | 8                | Y                   | -                          |
|             | Asynchronous | W   | 8             | 8                | Y                   | -                          |
|             | Asynchronous | R   | 16            | 8                | Y                   | Split into 2 FSMC accesses |
|             | Asynchronous | W   | 16            | 8                | Y                   | Split into 2 FSMC accesses |
|             | Asynchronous | R   | 32            | 8                | Y                   | Split into 4 FSMC accesses |
|             | Asynchronous | W   | 32            | 8                | Y                   | Split into 4 FSMC accesses |
| NAND 16-bit | Asynchronous | R   | 8             | 16               | Y                   | -                          |
|             | Asynchronous | W   | 8             | 16               | N                   | -                          |
|             | Asynchronous | R   | 16            | 16               | Y                   | -                          |
|             | Asynchronous | W   | 16            | 16               | Y                   | -                          |
|             | Asynchronous | R   | 32            | 16               | Y                   | Split into 2 FSMC accesses |
|             | Asynchronous | W   | 32            | 16               | Y                   | Split into 2 FSMC accesses |

### 36.6.3 Timing diagrams for NAND and PC Card

Each PC Card/CompactFlash and NAND Flash memory bank is managed through a set of registers:

- Control register: FSMC\_PCRx
- Interrupt status register: FSMC\_SRx
- ECC register: FSMC\_ECCRx
- Timing register for Common memory space: FSMC\_PMEMx
- Timing register for Attribute memory space: FSMC\_PATTx
- Timing register for I/O space: FSMC\_PIOx

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any PC Card/CompactFlash or NAND Flash access, plus one parameter that defines the timing for starting driving the databus in the case of a write. [Figure 454](#) shows the timing parameter definitions for common memory accesses, knowing that Attribute and I/O (only for PC Card) memory space access timings are similar.

Figure 454. NAND/PC Card controller timing for common memory access

1. NOE remains high (inactive) during write access. NWE remains high (inactive) during read access.
2. For write accesses, the hold phase delay is  $(MEMxHOLD) \times HCLK$  cycles, while it is  $(MEMxHOLD + 2) \times HCLK$  cycles for read accesses.

### 36.6.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash device are driven by some address signals of the FSMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a certain address in its memory space.

A typical page read operation from the NAND Flash device is as follows:

1. Program and enable the corresponding memory bank by configuring the FSMC\_PCRx and FSMC\_PMEMx (and for some devices, FSMC\_PATTx, see [Section 36.6.5](#)) registers according to the characteristics of the NAND Flash (PWID bits for the databus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see [Common memory space timing register 2.4 \(FSMC\\_PMEM2.4\)](#) for timing configuration).
2. The CPU performs a byte write in the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The CLE input of the NAND Flash is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash. Once the command is latched by the NAND Flash device, it does not need to be written for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing the required bytes (for example four bytes or three for smaller capacity devices), STARTAD[7:0], STARTAD[15:8], STARTAD[23:16] and finally STARTAD[25:24] for 64 Mb x 8 bit NAND Flash) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the

written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FSMC, which can be used to implement the prewait functionality needed by some NAND Flash memories (see details in [Section 36.6.5](#)).

4. The controller waits for the NAND Flash to be ready (R/NB signal high) to become active, before starting a new access (to same or another memory bank). While waiting, the controller maintains the NCE signal active (low).
5. The CPU can then perform byte read operations in the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.
6. The next NAND Flash page can be read without any CPU command or address write operation, in three different ways:
  - by simply performing the operation described in step 5
  - a new random address can be accessed by restarting the operation at step 3
  - a new command can be sent to the NAND Flash device by restarting at step 2

### 36.6.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller wait for the R/NB signal to go low as shown in [Figure 455](#).

**Figure 455. Access to non 'CE don't care' NAND-Flash**

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7-A0 at address 0x7002 0000.
3. CPU wrote byte A15-A8 at address 0x7002 0000.
4. CPU wrote byte A23-A16 at address 0x7002 0000.
5. CPU wrote byte A25-A14 at address 0x7802 0000: FSMC performs a write access using FSMC\_PATT2 timing definition, where  $ATTHOLD \geq 7$  (providing that  $(7+1) \times HCLK = 112 \text{ ns} > t_{WB} \text{ max}$ ). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don't care).

When this functionality is needed, it can be guaranteed by programming the MEMHOLD value to meet the  $t_{\text{WB}}$  timing. However CPU read accesses to the NAND Flash memory has a hold delay of  $(\text{MEMHOLD} + 2) \times \text{HCLK}$  cycles, while CPU write accesses have a hold delay of  $(\text{MEMHOLD}) \times \text{HCLK}$  cycles.

To overcome this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the  $t_{\text{WB}}$  timing, and leaving the MEMHOLD value at its minimum. Then, the CPU must use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

### 36.6.6 Computation of the error correction code (ECC) in NAND Flash memory

The FSMC PC-Card controller includes two error correction code computation hardware blocks, one per memory bank. They are used to reduce the host CPU workload when processing the error correction code by software in the system.

These two registers are identical and associated with bank 2 and bank 3, respectively. As a consequence, no hardware ECC computation is available for memories connected to bank 4.

The error correction code (ECC) algorithm implemented in the FSMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read from or written to NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash databus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The functional operations are:

- When access to NAND Flash is made to bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When access to NAND Flash occurs at any other address, the ECC logic is idle, and does not perform any operation. Thus, write operations for defining commands or addresses to NAND Flash are not taken into account for ECC computation.

Once the desired number of bytes has been read from/written to the NAND Flash by the host CPU, the FSMC\_ECCR2/3 registers must be read in order to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to zero. To compute a new data block, the ECCEN bit must be set to one in the FSMC\_PCR2/3 registers.

To perform an ECC computation:

1. Enable the ECCEN bit in the FSMC\_PCR2/3 register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FSMC\_ECCR2/3 register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FSMC\_PCR2/3 register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FSMC\_ECCR2/3 register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 36.6.7 PC Card/CompactFlash operations

#### Address spaces and memory accesses

The FSMC supports Compact Flash storage or PC Cards in Memory Mode and I/O Mode (True IDE mode is not supported).

The Compact Flash storage and PC Cards are made of 3 memory spaces:

- Common Memory Space
- Attribute Space
- I/O Memory Space

The nCE2 and nCE1 pins (FSMC\_NCE4\_2 and FSMC\_NCE4\_1 respectively) select the card and indicate whether a byte or a word operation is being performed: nCE2 accesses the odd byte on D15-8 and nCE1 accesses the even byte on D7-0 if A0=0 or the odd byte on D7-0 if A0=1. The full word is accessed on D15-0 if both nCE2 and nCE1 are low.

The memory space is selected by asserting low nOE for read accesses or nWE for write accesses, combined with the low assertion of nCE2/nCE1 and nREG.

- If pin nREG=1 during the memory access, the common memory space is selected
- If pin nREG=0 during the memory access, the attribute memory space is selected

The I/O Space is selected by asserting low nIORD for read accesses or nIOWR for write accesses [instead of nOE/nWE for memory Space], combined with nCE2/nCE1. Note that nREG must also be asserted low during accesses to I/O Space.

Three type of accesses are allowed for a 16-bit PC Card:

- Accesses to Common Memory Space for data storage can be either 8-bit accesses at even addresses or 16 bit AHB accesses.  
Note that 8-bit accesses at odd addresses are not supported and do not lead to the low assertion of nCE2. A 32-bit AHB request is translated into two 16-bit memory accesses.
- Accesses to Attribute Memory Space where the PC Card stores configuration information are limited to 8-bit AHB accesses at even addresses.  
Note that a 16-bit AHB access is converted into a single 8-bit memory transfer: nCE1 is asserted low, nCE2 is asserted high and only the even Byte on D7-D0 is valid. Instead

a 32-bit AHB access is converted into two 8-bit memory transfers at even addresses: nCE1 is asserted low, NCE2 is asserted high and only the even bytes are valid.

- Accesses to I/O Space can be performed either through AHB 8-bit or 16-bit accesses.

**Table 252. 16-bit PC-Card signals and access type**

| nCE2 | nCE1 | nREG | nOE/nWE | nIORD /nIOWR | A10 | A9 | A7-1 | A0 | Space               | Access Type                                    | Allowed/not Allowed |
|------|------|------|---------|--------------|-----|----|------|----|---------------------|------------------------------------------------|---------------------|
| 1    | 0    | 1    | 0       | 1            | X   | X  | X-X  | X  | Common Memory Space | Read/Write byte on D7-D0                       | YES                 |
| 0    | 1    | 1    | 0       | 1            | X   | X  | X-X  | X  |                     | Read/Write byte on D15-D8                      | Not supported       |
| 0    | 0    | 1    | 0       | 1            | X   | X  | X-X  | 0  |                     | Read/Write word on D15-D0                      | YES                 |
| X    | 0    | 0    | 0       | 1            | 0   | 1  | X-X  | 0  | Attribute Space     | Read or Write Configuration registers          | YES                 |
| X    | 0    | 0    | 0       | 1            | 0   | 0  | X-X  | 0  |                     | Read or Write CIS (Card Information Structure) | YES                 |
| 1    | 0    | 0    | 0       | 1            | X   | X  | X-X  | 1  | Attribute Space     | Invalid Read or Write (odd address)            | YES                 |
| 0    | 1    | 0    | 0       | 1            | X   | X  | X-X  | x  |                     | Invalid Read or Write (odd address)            | YES                 |
| 1    | 0    | 0    | 1       | 0            | X   | X  | X-X  | 0  | I/O space           | Read Even Byte on D7-0                         | YES                 |
| 1    | 0    | 0    | 1       | 0            | X   | X  | X-X  | 1  |                     | Read Odd Byte on D7-0                          | YES                 |
| 1    | 0    | 0    | 1       | 0            | X   | X  | X-X  | 0  |                     | Write Even Byte on D7-0                        | YES                 |
| 1    | 0    | 0    | 1       | 0            | X   | X  | X-X  | 1  |                     | Write Odd Byte on D7-0                         | YES                 |
| 0    | 0    | 0    | 1       | 0            | X   | X  | X-X  | 0  |                     | Read Word on D15-0                             | YES                 |
| 0    | 0    | 0    | 1       | 0            | X   | X  | X-X  | 0  |                     | Write word on D15-0                            | YES                 |
| 0    | 1    | 0    | 1       | 0            | X   | X  | X-X  | X  |                     | Read Odd Byte on D15-8                         | Not supported       |
| 0    | 1    | 0    | 1       | 0            | X   | X  | X-X  | X  |                     | Write Odd Byte on D15-8                        | Not supported       |

The FSMC Bank 4 gives access to those 3 memory spaces as described in [Section 36.4.2: NAND/PC Card address mapping](#) and [Table 219: Memory mapping and timing registers](#).

### Wait Feature

The CompactFlash Storage or PC Card may request the FSMC to extend the length of the access phase programmed by MEMWAITx/ATTWAITx/IOWAITx bits, asserting the nWAIT signal after nOE/nWE or nIORD/nIOWR activation if the wait feature is enabled through the PWAITEN bit in the FSMC\_PCRx register. In order to detect the nWAIT assertion correctly, the MEMWAITx/ATTWAITx/IOWAITx bits must be programmed as follows:

$xxWAITx \geq 4 + \text{max\_wait\_assertion\_time}/HCLK$

Where max\_wait\_assertion\_time is the maximum time taken by NWAIT to go low once nOE/nWE or nIORD/nIOWR is low.

After the de-assertion of nWAIT, the FSMC extends the WAIT phase for 4 HCLK clock cycles.

### 36.6.8 NAND Flash/PC Card control registers

The NAND Flash/PC Card control registers have to be accessed by words (32 bits).

#### PC Card/NAND Flash control registers 2..4 (FSMC\_PCR2..4)

Address offset:  $0xA0000000 + 0x40 + 0x20 * (x - 1)$ ,  $x = 2..4$

Reset value: 0x0000 0018

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19         | 18  | 17  | 16       | 15  | 14  | 13  | 12        | 11  | 10  | 9   | 8    | 7     | 6         | 5   | 4    | 3     | 2       | 1        | 0   |
|----------|----|----|----|----|----|----|----|----|----|----|----|------------|-----|-----|----------|-----|-----|-----|-----------|-----|-----|-----|------|-------|-----------|-----|------|-------|---------|----------|-----|
| Reserved |    |    |    |    |    |    |    |    |    |    |    | ECCPS[2:0] |     |     | TAR[2:0] |     |     |     | TCLR[2:0] |     |     |     | Res. | ECCEN | PWID[1:0] |     | PTYP | PBKEN | PWAITEN | Reserved |     |
|          |    |    |    |    |    |    |    |    |    |    |    | r/w        | r/w | r/w | r/w      | r/w | r/w | r/w | r/w       | r/w | r/w | r/w |      | r/w   | r/w       | r/w | r/w  | r/w   | r/w     |          | r/w |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]**: ECC page size.

Defines the page size for the extended ECC:

000: 256 bytes  
 001: 512 bytes  
 010: 1024 bytes  
 011: 2048 bytes  
 100: 4096 bytes  
 101: 8192 bytes

Bits 16:13 **TAR[2:0]**: ALE to RE delay.

Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).

Time is:  $t_{ar} = (TAR + SET + 2) \times THCLK$  where THCLK is the HCLK clock period

0000: 1 HCLK cycle (default)  
 1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 12:9 **TCLR[2:0]**: CLE to RE delay.

Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).

Time is:  $t_{clr} = (TCLR + SET + 2) \times THCLK$  where THCLK is the HCLK clock period

0000: 1 HCLK cycle (default)  
 1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN**: ECC computation logic enable bit

0: ECC logic is disabled and reset (default after reset),  
 1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Databus width.

Defines the external memory device width.

00: 8 bits

01: 16 bits (default after reset). This value is mandatory for PC Cards.

10: reserved, do not use

11: reserved, do not use

Bit 3 **PTYP**: Memory type.

Defines the type of device attached to the corresponding memory bank:

0: PC Card, CompactFlash, CF+ or PCMCIA

1: NAND Flash (default after reset)

Bit 2 **PBKEN**: PC Card/NAND Flash memory bank enable bit.

Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus

0: Corresponding memory bank is disabled (default after reset)

1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit.

Enables the Wait feature for the PC Card/NAND Flash memory bank:

0: disabled

1: enabled

*Note: For a PC Card, when the wait feature is enabled, the MEMWAITx/ATTWAITx/IOWAITx bits must be programmed to a value as follows:*

$xxWAITx \geq 4 + \frac{\text{max\_wait\_assertion\_time}}{HCLK}$

*Where max\_wait\_assertion\_time is the maximum time taken by NWAIT to go low once nOE/nWE or nIORD/nIOWR is low.*

Bit 0 Reserved, must be kept at reset value.

## FIFO status and interrupt register 2..4 (FSMC\_SR2..4)

Address offset:  $0xA000\ 0000 + 0x44 + 0x20 * (x-1)$ ,  $x = 2..4$

Reset value: 0x0000 0040

This register contains information about FIFO status and interrupt. The FSMC has a FIFO that is used when writing to memories to store up to 16 words of data from the AHB.

This is used to quickly write to the AHB and free it for transactions to peripherals other than the FSMC, while the FSMC is draining its FIFO into the memory. This register has one of its bits that indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory, so in order to read the correct ECC the software must wait until the FIFO is empty.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12    | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4    | 3 | 2 | 1 | 0 |  |  |  |      |  |  |  |  |  |  |  |      |  |  |  |  |  |  |  |     |  |  |  |  |  |  |  |     |  |  |  |  |  |  |  |     |  |  |  |  |  |  |  |

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT**: FIFO empty.

Read-only bit that provides the status of the FIFO  
0: FIFO not empty  
1: FIFO empty

Bit 5 **IFEN**: Interrupt falling edge detection enable bit

0: Interrupt falling edge detection request disabled  
1: Interrupt falling edge detection request enabled

Bit 4 **ILEN**: Interrupt high-level detection enable bit

0: Interrupt high-level detection request disabled  
1: Interrupt high-level detection request enabled

Bit 3 **IREN**: Interrupt rising edge detection enable bit

0: Interrupt rising edge detection request disabled  
1: Interrupt rising edge detection request enabled

Bit 2 **IFS**: Interrupt falling edge status

The flag is set by hardware and reset by software.  
0: No interrupt falling edge occurred  
1: Interrupt falling edge occurred

*Note: This bit is set by programming it to 1 by software.*

Bit 1 **ILS**: Interrupt high-level status

The flag is set by hardware and reset by software.  
0: No Interrupt high-level occurred  
1: Interrupt high-level occurred

Bit 0 **IRS**: Interrupt rising edge status

The flag is set by hardware and reset by software.  
0: No interrupt rising edge occurred  
1: Interrupt rising edge occurred

*Note: This bit is set by programming it to 1 by software.*

### Common memory space timing register 2..4 (FSMC\_PMEM2..4)

Address offset: Address:  $0xA000\ 0000 + 0x48 + 0x20 * (x - 1)$ ,  $x = 2..4$

Reset value: 0xFCFC FCFC

Each FSMC\_PMEMx ( $x = 2..4$ ) read/write register contains the timing information for PC Card or NAND Flash memory bank x, used for access to the common memory space of the 16-bit PC Card/CompactFlash, or to access the NAND Flash for command, address write access and data read/write access.

|             |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MEMHIZ[7:0] |    |    |    |    |    |    |    | MEMHOLD[7:0] |    |    |    |    |    |    |    | MEMWAIT[7:0] |    |    |    |    |    |    |    | MEMSET[7:0] |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW |

Bits 31:24 **MEMHIZx[7:0]**: Common memory x databus HiZ time

Defines the number of HCLK clock cycles during which the databus is kept in HiZ after the start of a PC Card/NAND Flash write access to common memory space on socket x. Only valid for write transaction:

0000 0000: 1 HCLK cycle  
 1111 1110: 255 HCLK cycles  
 1111 1111: Reserved

Bits 23:16 **MEMHOLDx[7:0]**: Common memory x hold time

For NAND Flash read accesses to the common memory space, these bits define the number of (HCLK+2) clock cycles during which the address is held after the command is deasserted (NWE, NOE).

For NAND Flash write accesses to the common memory space, these bits define the number of HCLK clock cycles during which the data are held after the command is deasserted (NWE, NOE).

0000 0000: Reserved  
 0000 0001: 1 HCLK cycle for write accesses, 3 HCLK cycles for read accesses  
 1111 1110: 254 HCLK cycle for write accesses, 256 HCLK cycles for read accesses  
 1111 1111: Reserved

Bits 15:8 **MEMWAITx[7:0]**: Common memory x wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for PC Card/NAND Flash read or write access to common memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: Reserved  
 0000 0001: 2 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)  
 1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)  
 1111 1111: Reserved.

Bits 7:0 **MEMSETx[7:0]**: Common memory x setup time

Defines the number of HCLK ( ) clock cycles to set up the address before the command assertion (NWE, NOE), for PC Card/NAND Flash read or write access to common memory space on socket x:

0000 0000: 1 HCLK cycle  
 1111 1110: 255 HCLK cycles  
 1111 1111: Reserved

## Attribute memory space timing registers 2..4 (FSMC\_PATT2..4)

Address offset:  $0xA000\ 0000 + 0x4C + 0x20 * (x - 1)$ ,  $x = 2..4$

Reset value: 0xFCFC FCFC

Each FSMC\_PATTx ( $x = 2..4$ ) read/write register contains the timing information for PC Card/CompactFlash or NAND Flash memory bank x. It is used for 8-bit accesses to the attribute memory space of the PC Card/CompactFlash or to access the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to [Section 36.6.5: NAND Flash prewait functionality](#)).

|             |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ATTHIZ[7:0] |    |    |    |    |    |    |    | ATTHOLD[7:0] |    |    |    |    |    |    |    | ATTWAIT[7:0] |    |    |    |    |    |    |    | ATTSET[7:0] |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW |

Bits 31:24 **ATTIHZ[7:0]**: Attribute memory x databus HiZ time

Defines the number of HCLK clock cycles during which the databus is kept in HiZ after the start of a PC CARD/NAND Flash write access to attribute memory space on socket x. Only valid for write transaction:

0000 0000: 0 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: Reserved.

Bits 23:16 **ATTHOLD[7:0]**: Attribute memory x hold time

For PC Card/NAND Flash read accesses to attribute memory space on socket x, these bits define the number of HCLK clock cycles (HCLK +2) clock cycles during which the address is held after the command is deasserted (NWE, NOE).

For PC Card/NAND Flash write accesses to attribute memory space on socket x, these bits define the number of HCLK clock cycles during which the data are held after the command is deasserted (NWE, NOE).

0000 0000: reserved

0000 0001: 1 HCLK cycle for write access, 3 HCLK cycles for read accesses

1111 1110: 254 HCLK cycle for write access, 256 HCLK cycles for read accesses

1111 1111: Reserved

Bits 15:8 **ATTWAIT[7:0]**: Attribute memory x wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for PC Card/NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: Reserved

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1111: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: Reserved.

Bits 7:0 **ATTSET[7:0]**: Attribute memory x setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for PC CARD/NAND Flash read or write access to attribute memory space on socket x:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: Reserved.

**I/O space timing register 4 (FSMC\_PIO4)**

Address offset: 0xA000 0000 + 0xB0

Reset value: 0xFCFCFCFC

The FSMC\_PIO4 read/write registers contain the timing information used to gain access to the I/O space of the 16-bit PC Card/CompactFlash.

|           |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

| IOHI[7:0] |    |    |    |    |    |    |    | IOHOLD[7:0] |    |    |    |    |    |    |    | IOWAIT[7:0] |    |    |    |    |    |    |    | IOSET[7:0] |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW | rW         | rW | rW | rW | rW | rW | rW | rW |

Bits 31:24 **IOHIZ[7:0]**: I/O x databus HiZ time

Defines the number of HCLK clock cycles during which the databus is kept in HiZ after the start of a PC Card write access to I/O space on socket x. Only valid for write transaction:

0000 0000: 0 HCLK cycle

1111 1111: 255 HCLK cycles (default value after reset)

Bits 23:16 **IOHOLD[7:0]**: I/O x hold time

Defines the number of HCLK clock cycles to hold address (and data for write access) after the command deassertion (NWE, NOE), for PC Card read or write access to I/O space on socket x:

0000 0000: reserved

0000 0001: 1 HCLK cycle

1111 1111: 255 HCLK cycles (default value after reset)

Bits 15:8 **IOWAIT[7:0]**: I/O x wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (SMNWE, SMNOE), for PC Card read or write access to I/O space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved, do not use this value

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1111: 256 HCLK cycles (+ wait cycle introduced by the Card deasserting NWAIT) (default value after reset)

Bits 7:0 **IOSET[7:0]**: I/O x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for PC Card read or write access to I/O space on socket x:

0000 0000: 1 HCLK cycle

1111 1111: 256 HCLK cycles (default value after reset)

**ECC result registers 2/3 (FSMC\_ECCR2/3)**

Address offset:  $0xA000\ 0000 + 0x54 + 0x20 * (x - 1)$ ,  $x = 2$  or  $3$

Reset value: 0x0000 0000

These registers contain the current error correction code value computed by the ECC computation modules of the FSMC controller (one module per NAND Flash memory bank). When the CPU reads the data from a NAND Flash memory page at the correct address (refer to [Section 36.6.6: Computation of the error correction code \(ECC\) in NAND Flash memory](#)), the data read from or written to the NAND Flash are processed automatically by ECC computation module. At the end of X bytes read (according to the ECCPS field in the FSMC\_PCRx registers), the CPU must read the computed ECC value from the FSMC\_ECCx registers, and then verify whether these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it if applicable. The FSMC\_ECCRx registers should be cleared after being read by setting the ECCEN bit to zero. For computing a new data block, the ECCEN bit must be set to one.

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

### 36.6.9 FSMC register map

The following table summarizes the FSMC registers.

**Table 254. FSMC register map**

| Offset | Register               | 31       | 30            | 29 | 28          | 27 | 26 | 25          | 24 | 23 | 22           | 21           | 20 | 19          | 18          | 17 | 16 | 15         | 14     | 13     | 12          | 11          | 10      | 9           | 8           | 7        | 6      | 5         | 4 | 3         | 2 | 1     | 0     |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 37 Flexible memory controller (FMC)

The Flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND/PC Card memory controller
- The Synchronous DRAM (SDRAM/Mobile LPDDR SDRAM) controller

This section applies to STM32F42xxx and STM32F43xxx only.

### 37.1 FMC main features

The FMC functional block makes the interface with synchronous and asynchronous static memories, SDRAM memories, and 16-bit PC memory cards. Its main purposes are:

- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - 16-bit PC Card compatible devices
  - Two banks of NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPDDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16- or 32-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write Data FIFO with 16 x 32-bit depth
- Write Address FIFO with 16 x 30-bit depth
- Cacheable Read FIFO with 6 x 32-bit depth (6 x 14-bit address tag) for SDRAM controller.

The FMC embeds two Write FIFOs: a Write Data FIFO with a 16x33-bit depth and a Write Address FIFO with a 16x30-bit depth.

- The Write Data FIFO stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- The Write Address FIFO stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the AHB burst is broken into two FIFO entries.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up. However, the settings can be changed at any time.

## 37.2 Block diagram

The FMC consists of five main blocks:

- The AHB interface (including the FMC configuration registers)
- The NOR Flash/PSRAM/SRAM controller
- The NAND Flash/PC Card controller
- The SDRAM controller
- The external device interface

The block diagram is shown in [Figure 456](#).

Figure 456. FMC block diagram

### 37.3 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC Chip Select (**FMC\_NEx**) does not toggle between consecutive accesses except when performing accesses in mode D with the extended mode enabled.

The FMC generates an AHB error in the following conditions:

- When reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC\_BCRx register.
- When reading or writing to the PC Card banks while the FMC\_CD input pin (Card Presence Detection) is low.
- When writing to a write protected SDRAM bank (WP bit set in the SDRAM\_SDCRx register).
- When the SDRAM address range is violated (access to reserved address range)

The effect of an AHB error depends on the AHB master which has attempted the R/W access:

- If the access has been attempted by the Cortex<sup>®</sup>-M4 with FPU CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

### 37.3.1 Supported memories and transactions

#### General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal  
There is no issue in this case.
- AHB transaction size is greater than the memory size:  
In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC Chip Select (FMC\_NEx) does not toggle between the consecutive accesses.
- AHB transaction size is smaller than the memory size:  
The transfer may or not be consistent depending on the type of external device:
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM, SDRAM)  
In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes BL[3:0].  
byte to be written are addressed by NBL[3:0].  
All memory byte are read (NBL[3:0] are driven low during read transaction) and the useless ones are discarded.
  - Accesses to devices that do not have the byte select feature (16-bit NOR and NAND Flash memories)  
This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in byte mode (only 16-bit words can be read/written from/to the Flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

### Configuration registers

The FMC can be configured through a set of registers. Refer to [Section 37.5.6](#), for a detailed description of the NOR Flash/PSRAM controller registers. Refer to [Section 37.6.8](#), for a detailed description of the NAND Flash/PC Card registers and to [Section 37.7.5](#) for a detailed description of the SDRAM controller registers.

## 37.4 External device address mapping

From the FMC point of view, the external memory is divided into 6 fixed-size banks of 256 Mbyte each (see [Figure 457](#)):

- Bank 1 used to address up to 4 NOR Flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Banks 2 and 3 used to address NAND Flash memory devices (1 device per bank)
- Bank 4 used to address a PC Card
- Bank 5 and 6 used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 457. FMC memory banks

### 37.4.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in [Table 255](#).

Table 255. NOR/PSRAM bank selection

| HADDR[27:26] <sup>(1)</sup> | Selected bank        |
|-----------------------------|----------------------|
| 00                          | Bank 1 - NOR/PSRAM 1 |
| 01                          | Bank 1 - NOR/PSRAM 2 |
| 10                          | Bank 1 - NOR/PSRAM 3 |
| 11                          | Bank 1 - NOR/PSRAM 4 |

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

**Table 256. NOR/PSRAM External memory address**

| Memory width <sup>(1)</sup> | Data address issued to the memory | Maximum memory capacity (bits) |
|-----------------------------|-----------------------------------|--------------------------------|
| 8-bit                       | HADDR[25:0]                       | 64 Mbyte x 8 = 512 Mbit        |
| 16-bit                      | HADDR[25:1] >> 1                  | 64 Mbyte/2 x 16 = 512 Mbit     |
| 32-bit                      | HADDR[25:2] >> 2                  | 64 Mbyte/4 x 32 = 512 Mbit     |

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC\_A[24:0]. In case of a 32-bit memory width, the FMC internally uses HADDR[25:2] to generate the external address.  
Whatever the external memory width, FMC\_A[0] should be connected to external memory address A[0].

### Wrap support for NOR Flash/PSRAM

Wrap burst mode for synchronous memories is not supported. The memories must be configured in linear burst mode of undefined length.

## 37.4.2 NAND Flash memory/PC Card address mapping

In this case, three banks are available, each of them being divided into memory areas as indicated in [Table 257](#).

**Table 257. NAND/PC Card memory mapping and timing registers**

| Start address | End address | FMC bank            | Memory space | Timing register  |
|---------------|-------------|---------------------|--------------|------------------|
| 0x9C00 0000   | 0x9FFF FFFF | Bank 4 - PC card    | I/O          | FMC_PIO4 (0xB0)  |
| 0x9800 0000   | 0x9BFF FFFF |                     | Attribute    | FMC_PATT4 (0xAC) |
| 0x9000 0000   | 0x93FF FFFF |                     | Common       | FMC_PMEM4 (0xA8) |
| 0x8800 0000   | 0x8BFF FFFF | Bank 3 - NAND Flash | Attribute    | FMC_PATT3 (0x8C) |
| 0x8000 0000   | 0x83FF FFFF |                     | Common       | FMC_PMEM3 (0x88) |
| 0x7800 0000   | 0x7BFF FFFF | Bank 2- NAND Flash  | Attribute    | FMC_PATT2 (0x6C) |
| 0x7000 0000   | 0x73FF FFFF |                     | Common       | FMC_PMEM2 (0x68) |

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in [Table 258](#) below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 258. NAND bank selection

| Section name    | HADDR[17:16] | Address range     |
|-----------------|--------------|-------------------|
| Address section | 1X           | 0x020000-0x03FFFF |
| Command section | 01           | 0x010000-0x01FFFF |
| Data section    | 00           | 0x000000-0x0FFFFF |

The application software uses the 3 sections to access the NAND Flash memory:

- **To send a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 byte long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

### 37.4.3 SDRAM address mapping

The HADDR[28] bit (internal AHB address line 28) is used to select one of the two memory banks as indicated in [Table 259](#).

Table 259. SDRAM bank selection

| HADDR[28] | Selected bank | Control register | Timing register |
|-----------|---------------|------------------|-----------------|
| 0         | SDRAM Bank1   | FMC_SDCR1        | FMC_SDTR1       |
| 1         | SDRAM Bank2   | FMC_SDCR2        | FMC_SDTR2       |

The following table shows SDRAM mapping for an 13-bit row ,a 11-bit column and 4 internal bank configurations.

Table 260. SDRAM address mapping

| Memory width <sup>(1)</sup> | Internal bank | Row address  | Column address <sup>(2)</sup> | Maximum memory capacity (Mbyte) |
|-----------------------------|---------------|--------------|-------------------------------|---------------------------------|
| 8-bit                       | HADDR[25:24]  | HADDR[23:11] | HADDR[10:0]                   | 64 Mbyte:<br>4 x 8K x 2K        |
| 16-bit                      | HADDR[26:25]  | HADDR[24:12] | HADDR[11:1]                   | 128 Mbyte:<br>4 x 8K x 2K x 2   |
| 32-bit                      | HADDR[27:26]  | HADDR[25:13] | HADDR[12:2]                   | 256 Mbyte:<br>4 x 8K x 2K x 4   |

1. When interfacing with a 16-bit memory, the FMC internally uses the HADDR[11:1] internal AHB address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses HADDR[12:2] lines to generate the external address. Whatever the memory width, FMC\_A[0] has to be connected to the external memory address A[0].
2. The AutoPrecharge is not supported. FMC\_A[10] must be connected to the external memory address A[10] but it is always driven 'low'.

The HADDR[27:0] bits are translated to external SDRAM address depending on the SDRAM controller configuration:

- Data size: 8, 16 or 32 bits
- Row size: 11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

[Table 261](#) to [Table 263](#) shows the SDRAM address mapping versus the SDRAM controller configuration.

**Table 261. SDRAM address mapping with 8-bit data bus width<sup>(1)(2)</sup>**

| Row size configuration        | HADDR(AHB Internal Address Lines) |    |            |            |            |            |            |            |           |           |    |    |    |    |              |              |              |             |             |             |   |   |   |   |   |   |   |   |
|-------------------------------|-----------------------------------|----|------------|------------|------------|------------|------------|------------|-----------|-----------|----|----|----|----|--------------|--------------|--------------|-------------|-------------|-------------|---|---|---|---|---|---|---|---|
|                               | 27                                | 26 | 25         | 24         | 23         | 22         | 21         | 20         | 19        | 18        | 17 | 16 | 15 | 14 | 13           | 12           | 11           | 10          | 9           | 8           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 11-bit row size configuration | Res.                              |    |            |            |            |            |            | Bank [1:0] |           | Row[10:0] |    |    |    |    |              |              |              |             |             | Column[7:0] |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            |            |            |            | Bank [1:0] |            | Row[10:0] |           |    |    |    |    |              |              |              |             | Column[8:0] |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            |            |            | Bank [1:0] |            | Row[10:0]  |           |           |    |    |    |    |              |              |              | Column[9:0] |             |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            |            | Bank [1:0] |            | Row[10:0]  |            |           |           |    |    |    |    |              |              | Column[10:0] |             |             |             |   |   |   |   |   |   |   |   |
| 12-bit row size configuration | Res.                              |    |            |            |            |            | Bank [1:0] |            | Row[11:0] |           |    |    |    |    |              |              |              |             | Column[7:0] |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            |            |            | Bank [1:0] |            | Row[11:0]  |           |           |    |    |    |    |              |              |              | Column[8:0] |             |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            |            | Bank [1:0] |            | Row[11:0]  |            |           |           |    |    |    |    |              |              | Column[9:0]  |             |             |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            | Bank [1:0] |            | Row[11:0]  |            |            |           |           |    |    |    |    |              | Column[10:0] |              |             |             |             |   |   |   |   |   |   |   |   |
| 13-bit row size configuration | Res.                              |    |            |            |            | Bank [1:0] |            | Row[12:0]  |           |           |    |    |    |    |              |              |              | Column[7:0] |             |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            |            | Bank [1:0] |            | Row[12:0]  |            |           |           |    |    |    |    |              |              | Column[8:0]  |             |             |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    |            | Bank [1:0] |            | Row[12:0]  |            |            |           |           |    |    |    |    |              | Column[9:0]  |              |             |             |             |   |   |   |   |   |   |   |   |
|                               | Res.                              |    | Bank [1:0] |            | Row[12:0]  |            |            |            |           |           |    |    |    |    | Column[10:0] |              |              |             |             |             |   |   |   |   |   |   |   |   |

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved (Res.) address range generates an AHB error.

Table 262. SDRAM address mapping with 16-bit data bus width<sup>(1)(2)</sup>

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.

2. Access to Reserved space (Res.) generates an AHB error.

3. BM0: is the byte mask for 16-bit access.

|                               | Bank [1:0]               |            | Row[12:0]  |           |           |    |    |    |    |    |    |    |    |    |    |    | Column[10:0] |             |             |   |   |   |   |   | BM[1:0] |         |         |   |

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AHB error.
3. BM[1:0]: is the byte mask for 32-bit access.

## 37.5 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC\_CLK) output.

The FMC Clock (FMC\_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous

and synchronous accesses depending on the CCKEN bit configuration in the FMC\_BCR1 register:

- If the CCKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC\_CLK continuous clock, Bank 1 must be configured in synchronous mode (see [Section 37.5.6: NOR/PSRAM controller registers](#)). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC\_CLK frequency is changed depending on AHB data transaction (refer to [Section 37.5.5: Synchronous transactions](#) for FMC\_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbyte. Each bank is configured through dedicated registers (see [Section 37.5.6: NOR/PSRAM controller registers](#)).

The programmable memory parameters include access times (see [Table 264](#)) and support for wait management (for PSRAM and NOR Flash accessed in burst mode).

**Table 264. Programmable NOR/PSRAM access parameters**

| Parameter          | Function                                                                         | Access mode                             | Unit                     | Min. | Max. |
|--------------------|----------------------------------------------------------------------------------|-----------------------------------------|--------------------------|------|------|
| Address setup      | Duration of the address setup phase                                              | Asynchronous                            | AHB clock cycle (HCLK)   | 0    | 15   |
| Address hold       | Duration of the address hold phase                                               | Asynchronous, muxed I/Os                | AHB clock cycle (HCLK)   | 1    | 15   |
| Data setup         | Duration of the data setup phase                                                 | Asynchronous                            | AHB clock cycle (HCLK)   | 1    | 256  |
| Bust turn          | Duration of the bus turnaround phase                                             | Asynchronous and synchronous read/write | AHB clock cycle (HCLK)   | 0    | 15   |
| Clock divide ratio | Number of AHB clock cycles (HCLK) to build one memory clock cycle (CLK)          | Synchronous                             | AHB clock cycle (HCLK)   | 2    | 16   |
| Data latency       | Number of clock cycles to issue to the memory before the first data of the burst | Synchronous                             | Memory clock cycle (CLK) | 2    | 17   |

### 37.5.1 External memory interface signals

[Table 265](#), [Table 266](#) and [Table 267](#) list the signals that are typically used to interface with NOR Flash memory, SRAM and PSRAM.

*Note:* The prefix “N” identifies the signals which are active low.

**NOR Flash memory, non-multiplexed I/Os****Table 265. Non-multiplexed I/O NOR Flash memory**

| FMC signal name | I/O | Function                                                                            |
|-----------------|-----|-------------------------------------------------------------------------------------|
| CLK             | O   | Clock (for synchronous access)                                                      |
| A[25:0]         | O   | Address bus                                                                         |
| D[31:0]         | I/O | Bidirectional data bus                                                              |
| NE[x]           | O   | Chip Select, x = 1..4                                                               |
| NOE             | O   | Output enable                                                                       |
| NWE             | O   | Write enable                                                                        |
| NL(=NADV)       | O   | Latch enable (this signal is called address valid, NADV, by some NOR Flash devices) |
| NWAIT           | I   | NOR Flash wait input signal to the FMC                                              |

The maximum capacity is 512 Mbits (26 address lines).

**NOR Flash memory, 16-bit multiplexed I/Os****Table 266. 16-bit multiplexed I/O NOR Flash memory**

| FMC signal name | I/O | Function                                                                                                                        |
|-----------------|-----|---------------------------------------------------------------------------------------------------------------------------------|
| CLK             | O   | Clock (for synchronous access)                                                                                                  |
| A[25:16]        | O   | Address bus                                                                                                                     |
| AD[15:0]        | I/O | 16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus) |
| NE[x]           | O   | Chip Select, x = 1..4                                                                                                           |
| NOE             | O   | Output enable                                                                                                                   |
| NWE             | O   | Write enable                                                                                                                    |
| NL(=NADV)       | O   | Latch enable (this signal is called address valid, NADV, by some NOR Flash devices)                                             |
| NWAIT           | I   | NOR Flash wait input signal to the FMC                                                                                          |

The maximum capacity is 512 Mbits.

**PSRAM/SRAM, non-multiplexed I/Os****Table 267. Non-multiplexed I/Os PSRAM/SRAM**

| FMC signal name | I/O | Function                                  |
|-----------------|-----|-------------------------------------------|
| CLK             | O   | Clock (only for PSRAM synchronous access) |
| A[25:0]         | O   | Address bus                               |
| D[31:0]         | I/O | Data bidirectional bus                    |

**Table 267. Non-multiplexed I/Os PSRAM/SRAM (continued)**

| FMC signal name | I/O | Function                                                             |
|-----------------|-----|----------------------------------------------------------------------|
| NE[x]           | O   | Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM)) |
| NOE             | O   | Output enable                                                        |
| NWE             | O   | Write enable                                                         |
| NL(= NADV)      | O   | Address valid only for PSRAM input (memory signal name: NADV)        |
| NWAIT           | I   | PSRAM wait input signal to the FMC                                   |
| NBL[3]          | O   | Byte3 Upper byte enable (memory signal name: NUB)                    |
| NBL[2]          | O   | Byte2 Lowed byte enable (memory signal name: NLB)                    |
| NBL[1]          | O   | Byte1 Upper byte enable (memory signal name: NLB)                    |
| NBL[0]          | O   | Byte0 Lower byte enable (memory signal name: NLB)                    |

The maximum capacity is 512 Mbits.

### PSRAM, 16-bit multiplexed I/Os

**Table 268. 16-Bit multiplexed I/O PSRAM**

| FMC signal name | I/O | Function                                                                                                                        |
|-----------------|-----|---------------------------------------------------------------------------------------------------------------------------------|
| CLK             | O   | Clock (for synchronous access)                                                                                                  |
| A[25:16]        | O   | Address bus                                                                                                                     |
| AD[15:0]        | I/O | 16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus) |
| NE[x]           | O   | Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))                                                            |
| NOE             | O   | Output enable                                                                                                                   |
| NWE             | O   | Write enable                                                                                                                    |
| NL(= NADV)      | O   | Address valid PSRAM input (memory signal name: NADV)                                                                            |
| NWAIT           | I   | PSRAM wait input signal to the FMC                                                                                              |
| NBL[1]          | O   | Upper byte enable (memory signal name: NUB)                                                                                     |
| NBL[0]          | O   | Lowed byte enable (memory signal name: NLB)                                                                                     |

The maximum capacity is 512 Mbits (26 address lines).

## 37.5.2 Supported memories and transactions

[Table 269](#) below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR Flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 269. NOR Flash/PSRAM: Example of supported memories and transactions

| Device                                               | Mode              | R/W | AHB data size | Memory data size | Allowed/not allowed | Comments                                                |
|------------------------------------------------------|-------------------|-----|---------------|------------------|---------------------|---------------------------------------------------------|
| NOR Flash<br>(muxed I/Os and nonmuxed I/Os)          | Asynchronous      | R   | 8             | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | W   | 8             | 16               | N                   | -                                                       |
|                                                      | Asynchronous      | R   | 16            | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | W   | 16            | 16               | Y                   | -                                                       |
|                                                      | Asynchronous      | R   | 32            | 16               | Y                   | Split into 2 FMC accesses                               |
|                                                      | Asynchronous      | W   | 32            | 16               | Y                   | Split into 2 FMC accesses                               |
|                                                      | Asynchronous page | R   | -             | 16               | N                   | Mode is not supported                                   |
|                                                      | Synchronous       | R   | 8             | 16               | N                   | -                                                       |
|                                                      | Synchronous       | R   | 16            | 16               | Y                   | -                                                       |
|                                                      | Synchronous       | R   | 32            | 16               | Y                   | -                                                       |
| PSRAM<br>(multiplexed I/Os and non-multiplexed I/Os) | Asynchronous      | R   | 8             | 16               | Y                   | -                                                       |

### 37.5.3 General timing rules

#### Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADV L/ NADV H /NBLL/ Address valid outputs change on the falling edge of FMC\_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC\_CLK clock.

### 37.5.4 NOR Flash/PSRAM controller asynchronous transactions

#### Asynchronous static memories (NOR Flash, PSRAM, SRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the extended mode is enabled (EXTMOD bit is set in the FMC\_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the extended mode is disabled (EXTMOD bit is reset in the FMC\_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP[1:0] = 0x0 or 0x01 in the FMC\_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP[1:0] = 0x10 in the FMC\_BCRx register).

### Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC\_BCRx, and FMC\_BTRx/FMC\_BWTRx registers.

**Figure 458. Mode1 read access waveforms**

**Figure 459. Mode1 write access waveforms**

The one HCLK cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this HCLK cycle, the DATAST value must be greater than zero (DATAST > 0).

**Table 270. FMC\_BCRx bit fields**

| Bit number | Bit name   | Value to set                                                       |
|------------|------------|--------------------------------------------------------------------|

### WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCAWAIT bit has to be set in FMC\_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET[3:0] and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$\text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time}$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):  
if

$$\text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}$$

then:

$$\text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase})$$

otherwise

$$\text{DATAST} \geq 4 \times \text{HCLK}$$

where max\_wait\_assertion\_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

Figure 471 and Figure 472 show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

**Figure 471. Asynchronous wait during a read access waveforms**

1. NWAIT polarity depends on WAITPOL bit setting in FMC\_BCRx register.

Figure 472. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC\_BCRx register.

### 37.5.5 Synchronous transactions

The memory clock, FMC\_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

$$\text{FMC\_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AHB data size}))$$

If MWID is 16 or 8 bits, the FMC\_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32 bits, the FMC\_CLK divider ratio depends also on AHB data size.

Example:

- If CLKDIV=1, MWID=32 bits, AHB data size=8 bits, FMC\_CLK=HCLK/4.
- If CLKDIV=1, MWID=16 bits, AHB data size=8 bits, FMC\_CLK=HCLK/2.

NOR Flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

### Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration

register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

### Single-burst transfer

When the selected bank is configured in burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

### Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC\_BCR1 register following the memory page size.

### Wait management

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR Flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC\_BCRx registers ( $x = 0..3$ ).

**Figure 473. Wait configuration waveforms**

**Figure 474. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)**

1. Byte lane outputs BL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access,

they are held low.

**Table 286. FMC\_BCRx bit fields**

| Bit No. | Bit name   | Value to set                                                                  |
|---------|------------|-------------------------------------------------------------------------------|
| 31-21   | Reserved   | 0x000                                                                         |
| 20      | CCLKEN     | As needed                                                                     |
| 19      | CBURSTRW   | No effect on synchronous read                                                 |
| 18-16   | CPSIZE     | As needed (0x1 for CRAM 1.5)                                                  |
| 15      | ASYNCAWAIT | 0x0                                                                           |
| 14      | EXTMOD     | 0x0                                                                           |
| 13      | WAITEN     | to be set to 1 if the memory supports this feature, to be kept at 0 otherwise |
| 12      | WREN       | no effect on synchronous read                                                 |
| 11      | WAITCFG    | to be set according to memory                                                 |
| 10      | WRAPMOD    | 0x0                                                                           |
| 9       | WAITPOL    | to be set according to memory                                                 |
| 8       | BURSTEN    | 0x1                                                                           |
| 7       | Reserved   | 0x1                                                                           |
| 6       | FACCEN     | Set according to memory support (NOR Flash memory)                            |
| 5-4     | MWID       | As needed                                                                     |
| 3-2     | MTYP[1:0]  | 0x1 or 0x2                                                                    |
| 1       | MUXEN      | As needed                                                                     |
| 0       | MBKEN      | 0x1                                                                           |

**Table 287. FMC\_BTRx bit fields**

| Bit No. | Bit name    | Value to set                                                             |
|---------|-------------|--------------------------------------------------------------------------|
| 31:30   | Reserved    | 0x0                                                                      |
| 29:28   | ACCMOD      | 0x0                                                                      |
| 27-24   | DATLAT      | Data latency                                                             |
| 27-24   | DATLAT      | Data latency                                                             |
| 23-20   | CLKDIV      | 0x0 to get CLK = HCLK (Not supported)<br>0x1 to get CLK = 2 × HCLK<br>.. |
| 19-16   | BUSTURN     | Time between NEx high to NEx low (BUSTURN HCLK)                          |
| 15-8    | DATAST      | Don't care                                                               |
| 7-4     | ADDHLD      | Don't care                                                               |
| 3-0     | ADDSET[3:0] | Don't care                                                               |

**Figure 475. Synchronous multiplexed write mode waveforms - PSRAM (CRAM)**

1. The memory must issue NWAIT signal one cycle in advance, accordingly WAITCFG must be programmed to 0.
2. Byte Lane (NBL) outputs are not shown, they are held low while NEx is active.

## 37.5.6 NOR/PSRAM controller registers

### SRAM/NOR-Flash chip-select control registers 1..4 (FMC\_BCR1..4)

Address offset:  $8 * (x - 1)$ ,  $x = 1...4$

Reset value: 0x0000 30DB for Bank1 and 0x0000 30D2 for Bank 2 to 4

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19       | 18          | 17 | 16 | 15        | 14     | 13     | 12   | 11      | 10      | 9       | 8       | 7        | 6      | 5         | 4  | 3  | 2         | 1  | 0     |       |    |
|----------|----|----|----|----|----|----|----|----|----|----|--------|----------|-------------|----|----|-----------|--------|--------|------|---------|---------|---------|---------|----------|--------|-----------|----|----|-----------|----|-------|-------|----|
| Reserved |    |    |    |    |    |    |    |    |    |    | CCLKEN | CBURSTRW | CPSIZE[2:0] |    |    | ASCYCWAIT | EXTMOD | WAITEN | WREN | WAITCFG | WRAPMOD | WAITPOL | BURSTEN | Reserved | FACCEN | MWID[1:0] |    |    | MTYP[1:0] |    | MUXEN | MBKEN |    |
|          |    |    |    |    |    |    |    |    |    |    | rw     | rw       |             |    |    | rw        | rw     | rw     | rw   | rw      | rw      | rw      | rw      |          | rw     | rw        | rw | rw | rw        | rw | rw    | rw    | rw |
|          |    |    |    |    |    |    |    |    |    |    | rw     | rw       |             |    |    | rw        | rw     | rw     | rw   | rw      | rw      | rw      | rw      |          | rw     | rw        | rw | rw | rw        | rw | rw    | rw    | rw |

Bits 31: 21 Reserved, must be kept at reset value

Bit 20 **CCLKEN**: Continuous Clock Enable.

This bit enables the FMC\_CLK clock output to external memory devices.

0: The FMC\_CLK is only generated during the synchronous memory access (read/write transaction). The FMC\_CLK clock ratio is specified by the programmed CLKDIV value in the FMC\_BCRx register (default after reset) .

1: The FMC\_CLK is generated continuously during asynchronous and synchronous access. The FMC\_CLK clock is activated when the CCLKEN is set.

*Note: The CCLKEN bit of the FMC\_BCR2..4 registers is don't care. It is only enabled through the FMC\_BCR1 register. Bank 1 must be configured in synchronous mode to generate the FMC\_CLK continuous clock.*

*Note: If CCLKEN bit is set, the FMC\_CLK clock ratio is specified by CLKDIV value in the FMC\_BTR1 register. CLKDIV in FMC\_BWTR1 is don't care.*

*Note: If the synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC\_BTR2..4 and FMC\_BWTR2..4 registers for other banks has no effect.)*

Bit 19 **CBURSTRW**: Write burst enable.

For PSRAM (CRAM) operating in burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC\_BCRx register.

0: Write operations are always performed in asynchronous mode

1: Write operations are performed in synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size.

These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset)

001: 128 bytes

010: 256 bytes

011: 512 bytes

100: 1024 bytes

Others: reserved

- Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers  
 This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.  
 0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)  
 1: NWAIT signal is taken in to account when running an asynchronous protocol
- Bit 14 **EXTMOD**: Extended mode enable.  
 This bit enables the FMC to program the write timings for non-multiplexed asynchronous accesses inside the FMC\_BWTR register, thus resulting in different timings for read and write operations.  
 0: values inside FMC\_BWTR register are not taken into account (default after reset)  
 1: values inside FMC\_BWTR register are taken into account  
*Note: When the extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:*  
 – Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP[1:0] = 0x0 or 0x01)  
 – Mode 2 is the default mode when the NOR memory type is selected (MTYP[1:0] = 0x10).
- Bit 13 **WAITEN**: Wait enable bit.  
 This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in synchronous mode.  
 0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period)  
 1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)
- Bit 12 **WREN**: Write enable bit.  
 This bit indicates whether write operations are enabled/disabled in the bank by the FMC:  
 0: Write operations are disabled in the bank by the FMC, an AHB error is reported,  
 1: Write operations are enabled for the bank by the FMC (default after reset).
- Bit 11 **WAITCFG**: Wait timing configuration.  
 The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:  
 0: NWAIT signal is active one data cycle before wait state (default after reset),  
 1: NWAIT signal is active during wait state (not used for PSRAM).
- Bit 10 **WRAPMOD**: Wrapped burst mode support.  
 Defines whether the controller splits or not an AHB burst wrap access into two linear accesses. Valid only when accessing memories in burst mode  
 0: Direct wrapped burst is not enabled (default after reset),  
 1: Direct wrapped burst is enabled.  
*Note: This bit has no effect as the CPU and DMA cannot generate wrapping burst transfers.*
- Bit 9 **WAITPOL**: Wait signal polarity bit.  
 Defines the polarity of the wait signal from memory used for either in synchronous or asynchronous mode:  
 0: NWAIT active low (default after reset),  
 1: NWAIT active high.
- Bit 8 **BURSTEN**: Burst enable bit.  
 This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in burst mode:  
 0: Burst mode disabled (default after reset). Read accesses are performed in asynchronous mode.  
 1: Burst mode enable. Read accesses are performed in synchronous mode.
- Bit 7 Reserved, must be kept at reset value

- Bit 6 **FACCEN**: Flash access enable  
 Enables NOR Flash memory access operations.  
 0: Corresponding NOR Flash memory access is disabled  
 1: Corresponding NOR Flash memory access is enabled (default after reset)
- Bits 5:4 **MWID[1:0]**: Memory data bus width.  
 Defines the external memory device width, valid for all type of memories.  
 00: 8 bits,  
 01: 16 bits (default after reset),  
 10: 32 bits,  
 11: reserved, do not use.
- Bits 3:2 **MTYP[1:0]**: Memory type.  
 Defines the type of external memory attached to the corresponding memory bank:  
 00: SRAM (default after reset for Bank 2...4)  
 01: PSRAM (CRAM)  
 10: NOR Flash/OneNAND Flash (default after reset for Bank 1)  
 11: reserved
- Bit 1 **MUXEN**: Address/data multiplexing enable bit.  
 When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:  
 0: Address/Data nonmultiplexed  
 1: Address/Data multiplexed on databus (default after reset)
- Bit 0 **MBKEN**: Memory bank enable bit.  
 Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.  
 0: Corresponding memory bank is disabled  
 1: Corresponding memory bank is enabled

### SRAM/NOR-Flash chip-select timing registers 1..4 (FMC\_BTR1..4)

Address offset:  $0x04 + 8 * (x - 1)$ ,  $x = 1..4$

Reset value: 0x0FFF FFFF

Reset value: 0x0FFF FFFF

FMC\_BTRx bits are written by software to add a delay at the end of a read /write transaction. This delay allows matching the minimum time between consecutive transactions ( $t_{EHEL}$  from NEx high to FMC\_NEx low) and the maximum time required by the memory to free the data bus after a read access ( $t_{EHQZ}$ ).

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories. If the EXTMOD bit is set in the FMC\_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC\_BWTRx registers).

Bits 31:30 Reserved, must be kept at reset value

Bits 29:28 **ACCMOD[1:0]**: Access mode

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC\_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:24 **DATLAT[3:0]**: Data latency for synchronous NOR Flash memory (see note below bit description table)

For synchronous accesses with read/write burst mode enabled (BURSTEN / CBURSTRW bits set), this field defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data. This timing parameter is not expressed in HCLK periods, but in FMC\_CLK periods. For asynchronous accesses, this value is don't care.

0000: Data latency of 2 CLK clock cycles for first burst access

1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]**: Clock divide ratio (for FMC\_CLK signal)

Defines the period of FMC\_CLK clock output signal, expressed in number of HCLK cycles:

0000: Reserved

0001: FMC\_CLK period = 2 × HCLK periods

0010: FMC\_CLK period = 3 × HCLK periods

1111: FMC\_CLK period = 16 × HCLK periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don't care.

*Note:* Refer to section [37.5.5: Synchronous transactions](#) for FMC\_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions ( $t_{\text{EHEL}}$  from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access ( $t_{\text{EHQZ}}$ ). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous /synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for modes muxed and D.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - Two consecutive asynchronous read transfers to the same static memory bank except for modes muxed and D.
  - An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for modes muxed and D.
  - An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read).
  - Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 HCLK clock cycle added

...

1111: BUSTURN phase duration = 15 x HCLK clock cycles added (default value after reset)

**Bits 15:8 DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to [Figure 458](#) to [Figure 470](#)), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × HCLK clock cycles

0000 0010: DATAST phase duration = 2 × HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

For each memory type and access mode data-phase duration, please refer to the respective figure ([Figure 458](#) to [Figure 470](#)).

Example: Mode1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

*Note: In synchronous accesses, this value is don't care.*

**Bits 7:4 ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 467](#) to [Figure 470](#)), used in mode D or multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × HCLK clock cycle

0010: ADDHLD phase duration = 2 × HCLK clock cycle

...

1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address-hold phase duration, please refer to the respective figure ([Figure 467](#) to [Figure 470](#)).

*Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.*

**Bits 3:0 ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to [Figure 458](#) to [Figure 470](#)), used in SRAMs, ROMs and asynchronous NOR Flash and PSRAM accesses:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address setup phase duration, please refer to the respective figure (refer to [Figure 458](#) to [Figure 470](#)).

*Note: In synchronous accesses, this value is don't care.*

*In Muxed mode or Mode D, the minimum value for ADDSET is 1.*

**Note:** *PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.*

*With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.*

*This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).*

**SRAM/NOR-Flash write timing registers 1..4 (FMC\_BWTR1..4)**

Address offset:  $0x104 + 8 * (x - 1)$ ,  $x = 1...4$

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC\_BCRx register, then this register is active for write access.

| 31       | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19           | 18 | 17 | 16 | 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3           | 2  | 1  | 0  |

Bits 31:30 Reserved, must be kept at reset value

Bits 29:28 **ACCMOD[1:0]**: Access mode.

Specifies the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC\_BCRx register is 1.

- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:20 Reserved, must be kept at reset value

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for modes muxed and D.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 HCLK clock cycle added

...

1111: BUSTURN phase duration = 15 HCLK clock cycles added (default value after reset)

Bits 15:8 **DATAST[3:0]**: Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to [Figure 458](#) to [Figure 470](#)), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × HCLK clock cycles

0000 0010: DATAST phase duration = 2 × HCLK clock cycles

...

1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to [Figure 467](#) to [Figure 470](#)), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × HCLK clock cycle

0010: ADDHLD phase duration = 2 × HCLK clock cycle

...

1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

*Note: In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.*

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in HCLK cycles (refer to [Figure 467](#) to [Figure 470](#)), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × HCLK clock cycle

...

1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

*Note: In synchronous NOR Flash and PSRAM accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.*

## 37.6 NAND Flash/PC Card controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND Flash memories
- 16-bit PC Card compatible devices

The NAND Flash/PC Card controller can control three external banks, Bank 2, 3 and 4:

- Bank 2 and Bank 3 support NAND Flash devices
- Bank 4 supports PC Card devices.

Each bank is configured through dedicated registers ([Section 37.6.8](#)). The programmable memory parameters include access timings (shown in [Table 290](#)) and ECC configuration.

**Table 290. Programmable NAND Flash/PC Card access parameters**

| Parameter             | Function                                                                                                                                                | Access mode | Unit                   | Min. | Max. |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------|------|------|
| Memory setup time     | Number of clock cycles (HCLK) required to set up the address before the command assertion                                                               | Read/Write  | AHB clock cycle (HCLK) | 1    | 256  |
| Memory wait           | Minimum duration (in HCLK clock cycles) of the command assertion                                                                                        | Read/Write  | AHB clock cycle (HCLK) | 2    | 255  |
| Memory hold           | Number of clock cycles (HCLK) during which the address must be held (as well as the data if a write access is performed) after the command de-assertion | Read/Write  | AHB clock cycle (HCLK) | 1    | 254  |
| Memory databus high-Z | Number of clock cycles (HCLK) during which the data bus is kept in high-Z state after a write access has started                                        | Write       | AHB clock cycle (HCLK) | 1    | 255  |

### 37.6.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND Flash memory and PC Card.

Note: The prefix "N" identifies the signals which are active low.

#### 8-bit NAND Flash memory

**Table 291. 8-bit NAND Flash**

| FMC signal name | I/O | Function                                             |
|-----------------|-----|------------------------------------------------------|
| A[17]           | O   | NAND Flash address latch enable (ALE) signal         |
| A[16]           | O   | NAND Flash command latch enable (CLE) signal         |
| D[7:0]          | I/O | 8-bit multiplexed, bidirectional address/data bus    |
| NCE[x]          | O   | Chip Select, x = 2, 3                                |
| NOE(= NRE)      | O   | Output enable (memory signal name: read enable, NRE) |
| NWE             | O   | Write enable                                         |
| NWAIT/INT[3:2]  | I   | NAND Flash ready/busy input signal to the FMC        |

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

**16-bit NAND Flash memory****Table 292. 16-bit NAND Flash**

| FMC signal name | I/O | Function                                             |
|-----------------|-----|------------------------------------------------------|
| A[17]           | O   | NAND Flash address latch enable (ALE) signal         |
| A[16]           | O   | NAND Flash command latch enable (CLE) signal         |
| D[15:0]         | I/O | 16-bit multiplexed, bidirectional address/data bus   |
| NCE[x]          | O   | Chip Select, x = 2, 3                                |
| NOE(= NRE)      | O   | Output enable (memory signal name: read enable, NRE) |
| NWE             | O   | Write enable                                         |
| NWAIT/INT[3:2]  | I   | NAND Flash ready/busy input signal to the FMC        |

*Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.*

**Table 293. 16-bit PC Card**

| FMC signal name | I/O | Function                                                                                                                                                                                 |
|-----------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A[10:0]         | O   | Address bus                                                                                                                                                                              |
| NIORD           | O   | Output enable for I/O space                                                                                                                                                              |
| NIOWR           | O   | Write enable for I/O space                                                                                                                                                               |
| NREG            | O   | Register signal indicating if access is in Common or Attribute space                                                                                                                     |
| D[15:0]         | I/O | Bidirectional databus                                                                                                                                                                    |
| NCE4_1          | O   | Chip Select 1                                                                                                                                                                            |
| NCE4_2          | O   | Chip Select 2 (indicates if access is 16-bit or 8-bit)                                                                                                                                   |
| NOE             | O   | Output enable in Common and in Attribute space                                                                                                                                           |
| NWE             | O   | Write enable in Common and in Attribute space                                                                                                                                            |
| NWAIT           | I   | PC Card wait input signal to the FMC (memory signal name IORDY)                                                                                                                          |
| INTR            | I   | PC Card interrupt to the FMC (only for PC Cards that can generate an interrupt)                                                                                                          |
| CD              | I   | PC Card presence detection. Active high. If an access is performed to the PC Card banks while CD is low, an AHB error is generated. Refer to <a href="#">Section 37.3: AHB interface</a> |

### 37.6.2 NAND Flash / PC Card supported memories and transactions

*Table 294 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND Flash / PC Card controller are shown in gray.*

**Table 294. Supported memories and transactions**

| Device      | Mode         | R/W | AHB data size | Memory data size | Allowed/not allowed | Comments                  |
|-------------|--------------|-----|---------------|------------------|---------------------|---------------------------|
| NAND 8-bit  | Asynchronous | R   | 8             | 8                | Y                   | -                         |
|             | Asynchronous | W   | 8             | 8                | Y                   | -                         |

### 37.6.3 Timing diagrams for NAND Flash memory and PC Card

Each PC Card/CompactFlash and NAND Flash memory bank is managed through a set of registers:

- Control register: FMC\_PCRx
- Interrupt status register: FMC\_SRx
- ECC register: FMC\_ECCRx
- Timing register for Common memory space: FMC\_PMEMx
- Timing register for Attribute memory space: FMC\_PATTx
- Timing register for I/O space: FMC\_PIOx

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any PC Card/CompactFlash or NAND Flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. [Figure 476](#) shows the timing parameter definitions for common memory accesses, knowing that Attribute and I/O (only for PC Card) memory space access timings are similar.

**Figure 476. NAND Flash/PC Card controller waveforms for common memory access**

1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write accesses, the hold phase delay is  $(MEMHOLD) \times HCLK$  cycles, while it is  $(MEMHOLD + 2) \times HCLK$  cycles for read accesses.

### 37.6.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

3. Program and enable the corresponding memory bank by configuring the FMC\_PCRx and FMC\_PMEMx (and for some devices, FMC\_PATTx, see [Section 37.6.5: NAND Flash prewait functionality](#)) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see [Section 37.4.2: NAND Flash memory/PC Card address mapping](#) for timing configuration).
4. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
5. The CPU can send the start address (STARTAD) for a read operation by writing four byte (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written byte are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used to

implement the prewait functionality needed by some NAND Flash memories (see details in [Section 37.6.5: NAND Flash prewait functionality](#)).

6. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
7. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.
8. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
  - by simply performing the operation described in step 5
  - a new random address can be accessed by restarting the operation at step 3
  - a new command can be sent to the NAND Flash device by restarting at step 2

### 37.6.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see [Figure 457](#)).

**Figure 477. Access to non 'CE don't care' NAND-Flash**

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7802 0000: FMC performs a write access using FMC\_PATT2 timing definition, where  $ATTHOLD \geq 7$  (providing that  $(7+1) \times HCLK = 112 \text{ ns} > t_{WB \text{ max}}$ ). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don't care).

When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the  $t_{WB}$  timing. However CPU read accesses to the NAND Flash memory has a hold delay of  $(MEMHOLD + 2) \times HCLK$  cycles, while CPU write accesses have a hold delay of  $(MEMHOLD) \times HCLK$  cycles.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the  $t_{WB}$  timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

### 37.6.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC PC Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 byte read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of byte has been read/written from/to the NAND Flash memory by the host CPU, the FMC\_ECCR2/3 registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to one in the FMC\_PCR2/3 registers.

To perform an ECC computation:

1. Enable the ECCEN bit in the FMC\_PCR2/3 register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC\_ECCR2/3 register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC\_PCR2/3 register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC\_ECCR2/3 register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 37.6.7 PC Card/CompactFlash operations

#### Address spaces and memory accesses

The FMC supports CompactFlash devices and PC Cards in Memory mode and I/O mode (True IDE mode is not supported).

The CompactFlash and PC Cards are made of 3 memory spaces:

- Common Memory space
- Attribute space
- I/O Memory space

The nCE2 and nCE1 pins (FMC\_NCE4\_2 and FMC\_NCE4\_1 respectively) select the card and indicate whether a byte or a word operation is being performed: nCE2 accesses the odd byte on D15-8 and nCE1 accesses the even byte on D7-0 if A0=0 or the odd byte on D7-0 if A0=1. The full word is accessed on D15-0 if both nCE2 and nCE1 are low.

The memory space is selected by asserting low nOE for read accesses or nWE for write accesses, combined with the low assertion of nCE2/nCE1 and nREG.

- If pin nREG=1 during the memory access, the common memory space is selected
- If pin nREG=0 during the memory access, the attribute memory space is selected

The I/O space is selected by asserting nIORD space for read accesses or nIOWR for write accesses [instead of nOE/nWE for memory space], combined with nCE2/nCE1. Note that nREG must also be asserted low when accessing I/O space.

Three type of accesses are allowed for a 16-bit PC Card:

- Accesses to Common Memory space for data storage can be either 8-bit accesses at even addresses or 16-bit AHB accesses.  
Note that 8-bit accesses at odd addresses are not supported and nCE2 is not driven low. A 32-bit AHB request is translated into two 16-bit memory accesses.
- Accesses to Attribute Memory space where the PC Card stores configuration information are limited to 8-bit AHB accesses at even addresses.  
Note that a 16-bit AHB access is converted into a single 8-bit memory transfer: nCE1 is asserted low, nCE2 is asserted high and only the even byte on D7-D0 are valid. Instead a 32-bit AHB access is converted into two 8-bit memory transfers at even addresses: nCE1 is asserted low, nCE2 is asserted high and only the even byte are valid.
- Accesses to I/O space can be either 8-bit or 16 bit AHB accesses.

Table 295. 16-bit PC-Card signals and access type

| nCE2 | nCE1 | nREG | nOE/nWE | nIORD | A10 | A9 | A7-1 | A0 | Space               | Access type                                    | Allowed/not Allowed |
|------|------|------|---------|-------|-----|----|------|----|---------------------|------------------------------------------------|---------------------|
| 1    | 0    | 1    | 0       | 1     | X   | X  | X-X  | X  | Common Memory Space | Read/Write byte on D7-D0                       | YES                 |
| 0    | 1    | 1    | 0       | 1     | X   | X  | X-X  | X  |                     | Read/Write byte on D15-D8                      | Not supported       |
| 0    | 0    | 1    | 0       | 1     | X   | X  | X-X  | 0  |                     | Read/Write word on D15-D0                      | YES                 |
| X    | 0    | 0    | 0       | 1     | 0   | 1  | X-X  | 0  | Attribute Space     | Read or Write Configuration Registers          | YES                 |
| X    | 0    | 0    | 0       | 1     | 0   | 0  | X-X  | 0  |                     | Read or Write CIS (Card Information Structure) | YES                 |
| 1    | 0    | 0    | 0       | 1     | X   | X  | X-X  | 1  | Attribute Space     | Invalid Read or Write (odd address)            | YES                 |
| 0    | 1    | 0    | 0       | 1     | X   | X  | X-X  | x  |                     | Invalid Read or Write (odd address)            | YES                 |
| 1    | 0    | 0    | 1       | 0     | X   | X  | X-X  | 0  | I/O space           | Read Even Byte on D7-0                         | YES                 |
| 1    | 0    | 0    | 1       | 0     | X   | X  | X-X  | 1  |                     | Read Odd Byte on D7-0                          | YES                 |
| 1    | 0    | 0    | 1       | 0     | X   | X  | X-X  | 0  |                     | Write Even Byte on D7-0                        | YES                 |
| 1    | 0    | 0    | 1       | 0     | X   | X  | X-X  | 1  |                     | Write Odd Byte on D7-0                         | YES                 |
| 0    | 0    | 0    | 1       | 0     | X   | X  | X-X  | 0  |                     | Read Word on D15-0                             | YES                 |
| 0    | 0    | 0    | 1       | 0     | X   | X  | X-X  | 0  |                     | Write word on D15-0                            | YES                 |
| 0    | 1    | 0    | 1       | 0     | X   | X  | X-X  | X  |                     | Read Odd Byte on D15-8                         | Not supported       |
| 0    | 1    | 0    | 1       | 0     | X   | X  | X-X  | X  |                     | Write Odd Byte on D15-8                        | Not supported       |

FMC Bank 4 gives access to those 3 memory spaces as described in [Section 37.4.2: NAND Flash memory/PC Card address mapping](#) and [Table 257: NAND/PC Card memory mapping and timing registers](#).

### Wait feature

The CompactFlash or PC Card may request the FMC to extend the length of the access phase programmed by MEMWAITx/ATTWAITx/IOWAITx bits, asserting the nWAIT signal after nOE/nWE or nIORD/nIOWR activation if the wait feature is enabled through the PWAITEN bit in the FMC\_PCRx register. To detect correctly the nWAIT assertion, the MEMWAITx/ATTWAITx/IOWAITx bits must be programmed as follows:

$$xxWAITx \geq 4 + \frac{\text{max\_wait\_assertion\_time}}{\text{HCLK}}$$

where max\_wait\_assertion\_time is the maximum time taken by nWAIT to go low once nOE/nWE or nIORD/nIOWR is low.

After WAIT de-assertion, the FMC extends the WAIT phase for 4 HCLK clock cycles.

## 37.6.8 NAND Flash/PC Card controller registers

### PC Card/NAND Flash control registers 2..4 (FMC\_PCR2..4)

Address offset:  $0x40 + 0x20 * (x - 1)$ ,  $x = 2..4$

Reset value: 0x0000 0018

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19         | 18 | 17 | 16       | 15 | 14 | 13 | 12        | 11 | 10 | 9 | 8        | 7 | 6     | 5  | 4         | 3  | 2    | 1     | 0       |          |
|----------|----|----|----|----|----|----|----|----|----|----|----|------------|----|----|----------|----|----|----|-----------|----|----|---|----------|---|-------|----|-----------|----|------|-------|---------|----------|
| Reserved |    |    |    |    |    |    |    |    |    |    |    | ECCPS[2:0] |    |    | TAR[3:0] |    |    |    | TCLR[3:0] |    |    |   | Reserved |   | ECCEN |    | PWID[1:0] |    | PTYP | PBKEN | PWAITEN | Reserved |
|          |    |    |    |    |    |    |    |    |    |    |    |            |    |    |          |    |    |    |           |    |    |   |          |   | rw    | rw | rw        | rw | rw   | rw    | rw      |          |

Bits 31:20 Reserved, must be kept at reset value

Bits 19:17 **ECCPS[2:0]**: ECC page size.

Defines the page size for the extended ECC:

000: 256 byte  
 001: 512 byte  
 010: 1024 byte  
 011: 2048 byte  
 100: 4096 byte  
 101: 8192 byte

Bits 16:13 **TAR[3:0]**: ALE to RE delay.

Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).

Time is:  $t_{ar} = (TAR + SET + 2) \times THCLK$  where THCLK is the HCLK clock period

0000: 1 HCLK cycle (default)  
 1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 12:9 **TCLR[3:0]**: CLE to RE delay.

Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).

Time is  $t_{clr} = (TCLR + SET + 2) \times THCLK$  where THCLK is the HCLK clock period

0000: 1 HCLK cycle (default)  
 1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value

Bit 6 **ECCEN**: ECC computation logic enable bit

0: ECC logic is disabled and reset (default after reset),  
 1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Data bus width.

Defines the external memory device width.

00: 8 bits  
 01: 16 bits (default after reset). This value is mandatory for PC Cards.  
 10: reserved, do not use  
 11: reserved, do not use

Bit 3 **PTYP**: Memory type.

Defines the type of device attached to the corresponding memory bank:

- 0: PC Card, CompactFlash, CF+ or PCMCIA
- 1: NAND Flash (default after reset)

Bit 2 **PBKEN**: PC Card/NAND Flash memory bank enable bit.

Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus

- 0: Corresponding memory bank is disabled (default after reset)
- 1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit.

Enables the Wait feature for the PC Card/NAND Flash memory bank:

- 0: disabled
- 1: enabled

*Note: For a PC Card, when the wait feature is enabled, the MEMWAITx/ATTWAITx/IOWAITx bits must be programmed to a value as follows:*

$$xxWAITx \geq 4 + \max\_wait\_assertion\_time/HCLK$$

*Where max\_wait\_assertion\_time is the maximum time taken by NWAIT to go low once nOE/nWE or nIORD/nIOWR is low.*

Bit 0 Reserved.

### FIFO status and interrupt register 2..4 (FMC\_SR2..4)

Address offset:  $0x44 + 0x20 * (x-1)$ ,  $x = 2..4$

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |       |      |      |      |     |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|-------|------|------|------|-----|-----|-----|

Bits 31:7 Reserved, must be kept at reset value

Bit 6 **FEMPT**: FIFO empty.

Read-only bit that provides the status of the FIFO

- 0: FIFO not empty
- 1: FIFO empty

Bit 5 **IFEN**: Interrupt falling edge detection enable bit

- 0: Interrupt falling edge detection request disabled
- 1: Interrupt falling edge detection request enabled

- Bit 4 **ILEN**: Interrupt high-level detection enable bit  
 0: Interrupt high-level detection request disabled  
 1: Interrupt high-level detection request enabled
- Bit 3 **IREN**: Interrupt rising edge detection enable bit  
 0: Interrupt rising edge detection request disabled  
 1: Interrupt rising edge detection request enabled
- Bit 2 **IFS**: Interrupt falling edge status  
 The flag is set by hardware and reset by software.  
 0: No interrupt falling edge occurred  
 1: Interrupt falling edge occurred

*Note: This bit is set by programming it to 1 by software.*

- Bit 1 **ILS**: Interrupt high-level status  
 The flag is set by hardware and reset by software.  
 0: No Interrupt high-level occurred  
 1: Interrupt high-level occurred
- Bit 0 **IRS**: Interrupt rising edge status  
 The flag is set by hardware and reset by software.  
 0: No interrupt rising edge occurred  
 1: Interrupt rising edge occurred

*Note: This bit is set by programming it to 1 by software.*

### Common memory space timing register 2..4 (FMC\_PMEM2..4)

Address offset: Address:  $0x48 + 0x20 * (x - 1)$ ,  $x = 2..4$

Reset value: 0xFCFC FCFC

Each FMC\_PMEMx ( $x = 2..4$ ) read/write register contains the timing information for PC Card or NAND Flash memory bank x. This information is used to access either the common memory space of the 16-bit PC Card/CompactFlash, or the NAND Flash for command, address write access and data read/write access.

|             |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MEMHIZ[7:0] |    |    |    |    |    |    |    | MEMHOLD[7:0] |    |    |    |    |    |    |    | MEMWAIT[7:0] |    |    |    |    |    |    |    | MEMSET[7:0] |    |    |    |    |    |    |    |
| rW          | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW |

Bits 31:24 **MEMHIZ[7:0]**: Common memory x data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept Hi-Z after the start of a PC Card/NAND Flash write access to common memory space on socket x. This is only valid for write transactions:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: Reserved.

Bits 23:16 **MEMHOLD[7:0]**: Common memory x hold time

For NAND Flash read accesses to the common memory space, these bits define the number of (HCLK+2) clock cycles during which the address is held after the command is deasserted (NWE, NOE).

For NAND Flash write accesses to the common memory space, these bits define the number of HCLK clock cycles during which the data are held after the command is deasserted (NWE, NOE).

0000 0000: reserved

0000 0001: 1 HCLK cycle for write accesses, 3 HCLK cycles for read accesses

1111 1110: 254 HCLK cycle for write accesses, 256 HCLK cycles for read accesses

1111 1111: Reserved.

Bits 15:8 **MEMWAIT[7:0]**: Common memory x wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for PC Card/NAND Flash read or write access to common memory space on socket x. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: Reserved

Bits 7:0 **MEMSET[7:0]**: Common memory x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for PC Card/NAND Flash read or write access to common memory space on socket x:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: Reserved.

## Attribute memory space timing registers 2..4 (FMC\_PATT2..4)

Address offset:  $0x4C + 0x20 * (x - 1)$ ,  $x = 2..4$

Reset value: 0xFCFC FCFC

Each FMC\_PATTx ( $x = 2..4$ ) read/write register contains the timing information for PC Card/CompactFlash or NAND Flash memory bank x. It is used for 8-bit accesses to the attribute memory space of the PC Card/CompactFlash or to access the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to [Section 37.6.5: NAND Flash prewait functionality](#)).

|             |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |   |
|-------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|---|

| rW          | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW           | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW |   |

Bits 31:24 **ATTHIZ[7:0]**: Attribute memory x data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a PC CARD/NAND Flash write access to attribute memory space on socket x. Only valid for write transaction:

0000 0000: 0 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: Reserved.

Bits 23:16 **ATTHOLD[7:0]**: Attribute memory x hold time

For PC Card/NAND Flash read accesses to attribute memory space on socket x, these bits define the number of HCLK clock cycles (HCLK +2) clock cycles during which the address is held after the command is deasserted (NWE, NOE).

For PC Card/NAND Flash write accesses to attribute memory space on socket x, these bits define the number of HCLK clock cycles during which the data are held after the command is deasserted (NWE, NOE).

0000 0000: Reserved

0000 0001: 1 HCLK cycle for write access, 3 HCLK cycles for read accesses

1111 1110: 254 HCLK cycle for write access, 256 HCLK cycles for read accesses

1111 1111: Reserved.

Bits 15:8 **ATTWAIT[7:0]**: Attribute memory x wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for PC Card/NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 HCLK cycles (+ wait cycle introduced by the card deasserting NWAIT)

1111 1111: Reserved

Bits 7:0 **ATTSET[7:0]**: Attribute memory x setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for PC CARD/NAND Flash read or write access to attribute memory space on socket x:

0000 0000: 1 HCLK cycle

1111 1110: 255 HCLK cycles

1111 1111: Reserved

**I/O space timing register 4 (FMC\_PIO4)**

Address offset: 0xB0

Reset value: 0xFCFCFCFC

The FMC\_PIO4 read/write registers contain the timing information used to access the I/O space of the 16-bit PC Card/CompactFlash.

|            |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |            |    |    |    |    |    |    |    |

| IOHIZ[7:0] |    |    |    |    |    |    |    | IOHOLD[7:0] |    |    |    |    |    |    |    | IOWAIT[7:0] |    |    |    |    |    |    |    | IOSET[7:0] |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW | rW          | rW | rW | rW | rW | rW | rW | rW | rW         | rW | rW | rW | rW | rW | rW | rW |

**Bits 31:24 IOHIZ[7:0]:** I/O x data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a PC Card write access to I/O space on socket x. Only valid for write transaction:

0000 0000: 0 HCLK cycle

1111 1111: 255 HCLK cycles

**Bits 23:16 IOHOLD[7:0]:** I/O x hold time

Defines the number of HCLK clock cycles during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for PC Card read or write access to I/O space on socket x:

0000 0000: reserved

0000 0001: 1 HCLK cycle

1111 1111: 255 HCLK cycles

**Bits 15:8 IOWAIT[7:0]:** I/O x wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (SMNWE, SMNOE), for PC Card read or write access to I/O space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

0000 0000: reserved, do not use this value

0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1111: 256 HCLK cycles (+ wait cycle introduced by the Card deasserting NWAIT)

**Bits 7:0 IOSET[7:0]:** I/O x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for PC Card read or write access to I/O space on socket x:

0000 0000: 1 HCLK cycle

1111 1111: 256 HCLK cycles

**ECC result registers 2/3 (FMC\_ECCR2/3)**

Address offset:  $0x54 + 0x20 * (x - 1)$ ,  $x = 2$  or  $3$

Reset value: 0x0000 0000

These registers contain the current error correction code value computed by the ECC computation modules of the FMC controller (one module per NAND Flash memory bank). When the CPU reads the data from a NAND Flash memory page at the correct address (refer to [Section 37.6.6: Computation of the error correction code \(ECC\) in NAND Flash memory](#)), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X byte have been read (according to the ECCPS field in the FMC\_PCRx registers), the CPU must read the computed ECC value from the FMC\_ECCx registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC\_ECCRx registers should be cleared after being read by setting the ECCEN bit to '0'. To compute a new data block, the ECCEN bit must be set to '1'.

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

## 37.7 SDRAM controller

### 37.7.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be HCLK/2 or HCLK/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

### 37.7.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must be configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

**Table 297. SDRAM signals**

| SDRAM signal | I/O type | Description                                                            | Alternate function |
|--------------|----------|------------------------------------------------------------------------|--------------------|
| SDCLK        | O        | SDRAM clock                                                            | -                  |

### 37.7.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC\_SDCLK).

#### SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1 and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC\_SDCMR register:

1. Program the memory device features into the FMC\_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC\_SDCR1 register.
2. Program the memory device timing into the FMC\_SDTRx register. The TRP and TRC timings must be programmed in the FMC\_SDTR1 register.
3. Set MODE bits to '001' and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100  $\mu$ s (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to '010' and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to issue a "Precharge All" command.
6. Set MODE bits to '011', and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC\_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field according to your SDRAM device, set the MODE bits to '100', and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register to issue a "Load Mode Register" command in order to program the SDRAM. In particular:
  - a) The CAS latency must be selected following configured value in FMC\_SDCR1/2 registers
  - b) The Burst Length (BL) of 1 must be selected by configuring the M[2:0] bits to 000 in the mode register (refer to the SDRAM datasheet). If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank, and the Target Bank bits set accordingly.
8. Program the refresh rate in the FMC\_SDRTR register  
The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.
9. For mobile SDRAM devices, to program the extended mode register it should be done once the SDRAM device is initialized: First, a dummy read access should be performed while BA1=1 and BA=0 (refer to SDRAM address mapping section for BA[1:0] address mapping) in order to select the extended mode register instead of Load mode register and then program the needed value.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefore the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR Flash/PSRAM/SRAM or NAND Flash/PC Card controller.

**Note:** *If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register and Self-refresh*

commands) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD, TRAS and TXSR timings) in the FMC\_SDTR1 register.

### SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC\_SDCRx register.

**Figure 478. Burst write SDRAM access waveforms**

The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

## SDRAM controller read cycle

The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

**Figure 479. Burst read SDRAM access**

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period and during the RPIPE delay. The following formula is applied:

$$\text{Number of anticipated data} = \text{CAS latency} + 1 + (\text{RPIPE delay}) / 2$$

The RBURST bit must be set in the FMC\_SDCR1 register to anticipate the next read access.

Example:

- CAS latency = 3, RPIPE delay = 0: 4 data (not committed) are stored in the FIFO.
- CAS latency = 3, RPIPE delay = 2: 5 data (not committed) are stored in the FIFO.

The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an AHB burst read, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

**Figure 480. Logic diagram of Read access with RBURST bit set (CAS=2, RPIPE=0)**

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to '1' in the FMC\_SDCR1 register.

The address management depends on the next AHB request:

- Next AHB request is sequential (AHB Burst)  
In this case, the SDRAM controller increments the address.
- Next AHB request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RURST is reset, the read FIFO is not used.

### Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC\_SDTRx register.

Refer to [Figure 481](#) and [Figure 482](#) for read and burst write access crossing a row boundary.

Figure 481. Read access crossing row boundary

Figure 482. Write access crossing row boundary

If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged. At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- For 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, if the current bank is the last one and the selected SDRAM device is connected to Bank 1, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  - a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  - b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

*Note: At bank boundary, if the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AHB error is generated.*

### SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC\_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = '1').

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC\_SDCMR Command Mode register (Mode bits = '011'), a PALL command (Mode bits = '010') must be issued first.

### 37.7.4 Low power modes

Two low power modes are available:

- Self-refresh mode  
The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode  
The auto-refresh cycles are performed by the SDRAM controller.

#### Self-refresh mode

This mode is selected by setting the MODE bits to '101' and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.

In Self-refresh mode, all SDRAM device inputs become don't care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC\_SDCMR register.

Figure 483. Self-refresh mode

### Power-down mode

This mode is selected by setting the MODE bits to '110' and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC\_SDCMR register.

Figure 484. Power-down mode

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to '000' (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC\_SDCMR register.

### 37.7.5 SDRAM controller registers

#### SDRAM Control registers 1,2 (FMC\_SDCR1,2)

Address offset:  $0x140 + 4 * (x - 1)$ ,  $x = 1, 2$

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14         | 13 | 12     | 11         | 10 | 9  | 8        | 7  | 6  | 5         | 4  | 3       | 2  | 1       | 0  |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|--------|------------|----|----|----------|----|----|-----------|----|---------|----|---------|----|
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RPIPE[1:0] |    | RBURST | SDCLK[1:0] |    | WP | CAS[1:0] |    | NB | MWID[1:0] |    | NR[1:0] |    | NC[1:0] |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rW         | rW | rW     | rW         | rW | rW | rW       | rW | rW | rW        | rW | rW      | rW | rW      | rW |

Bits 31:15 Reserved, must be kept at reset value

Bits 14:13 **RPIPE[1:0]**: Read pipe

These bits define the delay, in HCLK clock cycles, for reading data after CAS latency.

- 00: No HCLK clock cycle delay
- 01: One HCLK clock cycle delay
- 10: Two HCLK clock cycle delay
- 11: reserved, do not use

*Note: The corresponding bits in the FMC\_SDCR2 register are read only.*

Bit 12 **RBURST**: Burst read

This bit enables burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.

- 0: single read requests are not managed as bursts
- 1: single read requests are always managed as bursts

Note: The corresponding bit in the FMC\_SDCR2 register is don't care.

Bits 11:10 **SDCLK[1:0]**: SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.

- 00: SDCLK clock disabled
- 01: Reserved
- 10: SDCLK period = 2 x HCLK periods
- 11: SDCLK period = 3 x HCLK periods

*Note: The corresponding bits in the FMC\_SDCR2 register are read only.*

Bit 9 **WP**: Write protection

This bit enables write mode access to the SDRAM bank.

- 0: Write accesses allowed
- 1: Write accesses ignored

Bits 8:7 **CAS[1:0]**: CAS Latency

This bits sets the SDRAM CAS latency in number of memory clock cycles

- 00: reserved, do not use.
- 01: 1 cycle
- 10: 2 cycles
- 11: 3 cycles

Bit 6 **NB**: Number of internal banks

This bit sets the number of internal banks.

0: Two internal Banks

1: Four internal Banks

Bits 5:4 **MWID[1:0]**: Memory data bus width.

These bits define the memory device width.

00: 8 bits

01: 16 bits

10: 32 bits

11: reserved, do not use.

Bits 3:2 **NR[1:0]**: Number of row address bits

These bits define the number of bits of a row address.

00: 11 bit

01: 12 bits

10: 13 bits

11: reserved, do not use.

Bits 1:0 **NC[1:0]**: Number of column address bits

These bits define the number of bits of a column address.

00: 8 bits

01: 9 bits

10: 10 bits

11: 11 bits.

**Note:** *Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.*

### SDRAM Timing registers 1,2 (FMC\_SDTR1,2)

Address offset:  $0x148 + 4 * (x - 1)$ ,  $x = 1,2$

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

|          |    |    |    |           |    |    |    |          |    |    |    |          |    |    |    |          |    |    |    |           |    |    |    |           |    |    |    |           |    |    |    |
|----------|----|----|----|-----------|----|----|----|----------|----|----|----|----------|----|----|----|----------|----|----|----|-----------|----|----|----|-----------|----|----|----|-----------|----|----|----|
| 31       | 30 | 29 | 28 | 27        | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19       | 18 | 17 | 16 | 15       | 14 | 13 | 12 | 11        | 10 | 9  | 8  | 7         | 6  | 5  | 4  | 3         | 2  | 1  | 0  |
| Reserved |    |    |    | TRCD[3:0] |    |    |    | TRP[3:0] |    |    |    | TWR[3:0] |    |    |    | TRC[3:0] |    |    |    | TRAS[3:0] |    |    |    | TXSR[3:0] |    |    |    | TMRD[3:0] |    |    |    |
| rW       | rW | rW | rW | rW        | rW | rW | rW | rW       | rW | rW | rW | rW       | rW | rW | rW | rW       | rW | rW | rW | rW        | rW | rW | rW | rW        | rW | rW | rW | rW        | rW | rW | rW |

Bits 31:28 Reserved, must be kept at reset value

Bits 27:24 **TRCD[3:0]**: Row to column delay

These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.

0000: 1 cycle.

0001: 2 cycles

....

1111: 16 cycles

Bits 23:20 **TRP[3:0]**: Row precharge delay

These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: The corresponding bits in the FMC\_SDTR2 register are don't care.*

Bits 19:16 **TWR[3:0]**: Recovery delay

These bits define the delay between a Write and a Precharge command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: TWR must be programmed to match the write recovery time ( $t_{WR}$ ) defined in the SDRAM datasheet, and to guarantee that:*

$$TWR \geq TRAS - TRCD \text{ and } TWR \geq TRC - TRCD - TRP$$

*Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR >= 2 cycles. TWR must be programmed to 0x1.*

*If two SDRAM devices are used, the FMC\_SDTR1 and FMC\_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.*

Bits 15:12 **TRC[3:0]**: Row cycle delay

These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

*Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.*

*Note: The corresponding bits in the FMC\_SDTR2 register are don't care.*

Bits 11:8 **TRAS[3:0]**: Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 7:4 **TXSR[3:0]**: Exit Self-refresh delay

These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

Bits 3:0 **TMRD[3:0]**: Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.

0000: 1 cycle

0001: 2 cycles

....

1111: 16 cycles

**Note:** *If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register and Self-refresh commands) are issued using the timing parameters configured for Bank 1 (TMRD, TRAS and TXSR timings) in the FMC\_SDTR1 register.*

*The TRP and TRC timings are only configured in the FMC\_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.*

### SDRAM Command Mode register (FMC\_SDCMR)

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command is issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21        | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9         | 8  | 7  | 6  | 5    | 4    | 3         | 2  | 1  | 0  |
|----------|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|------|------|-----------|----|----|----|
| Reserved |    |    |    |    |    |    |    |    |    | MRD[11:0] |    |    |    |    |    |    |    |    |    |    |    | NRFS[3:0] |    |    |    | CTB1 | CTB2 | MODE[2:0] |    |    |    |
|          |    |    |    |    |    |    |    |    |    | rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW        | rW | rW | rW | rW   | rW   | rW        | rW | rW | rW |

Bits 31:22 Reserved, must be kept at reset value

Bits 21:9 **MRD[11:0]**: Mode Register definition

This 13-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command.

Bits 8:5 **NRFS[3:0]**: Number of Auto-refresh

These bits define the number of consecutive Auto-refresh commands issued when MODE = '011'.

0000: 1 Auto-refresh cycle

0001: 2 Auto-refresh cycles

....

1110: 15 Auto-refresh cycles

1111: Reserved

Bit 4 **CTB1**: Command Target Bank 1

This bit indicates whether the command is issued to SDRAM Bank 1 or not.

0: Command not issued to SDRAM Bank 1

1: Command issued to SDRAM Bank 1

Bit 3 **CTB2**: Command Target Bank 2

This bit indicates whether the command is issued to SDRAM Bank 2 or not.

- 0: Command not issued to SDRAM Bank 2
- 1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]**: Command mode

These bits define the command issued to the SDRAM device.

- 000: Normal Mode
- 001: Clock Configuration Enable
- 010: PALL ("All Bank Precharge") command
- 011: Auto-refresh command
- 100: Load Mode Register
- 101: Self-refresh command
- 110: Power-down command
- 111: Reserved

*Note: When a command is issued, at least one Command Target Bank bit ( CBT1 or CBT2) must be set. If both banks are used, the commands must be issued to the two banks at the same time by setting the CBT1 and CBT2 bits.*

### SDRAM Refresh Timer register (FMC\_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{SDRAM refresh rate} \times \text{SDRAM clock frequency}) - 20$$

$$\text{SDRAM refresh rate} = \text{SDRAM refresh period} / \text{Number of rows}$$

### Example

$$\text{SDRAM refresh rate} = 64 \text{ ms} / (8196 \text{ rows}) = 7.81 \mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81 \mu\text{s} \times 60 \text{ MHz} = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC\_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register common to SDRAM bank 1 and bank 2.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |      |    |             |    |    |    |    |    |    |    |    |    |    |    |     |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|-------------|----|----|----|----|----|----|----|----|----|----|----|-----|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14   | 13 | 12          | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0   |   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | REIE |    | COUNT[12:0] |    |    |    |    |    |    |    |    |    |    |    | CRE |   |

Bits 31: 15 Reserved, must be kept at reset value

Bit 14 **REIE**: RES Interrupt Enable

0: Interrupt is disabled

1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]**: Refresh Timer Count

This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 41 SDRAM clock cycles (0x29).

$COUNT = (SDRAM \text{ refresh rate} \times SDRAM \text{ clock frequency}) - 20$

$SDRAM \text{ refresh rate} = SDRAM \text{ refresh period} / \text{Number of rows}$

Bit 0 **CRE**: Clear Refresh error flag

This bit is used to clear the Refresh Error Flag (RE) in the Status Register.

0: no effect

1: Refresh Error flag is cleared

**Note:** *The programmed COUNT value must not be equal to the sum of the following timings:  $TWR + TRP + TRC + TRCD + 4$  memory clock cycles.*

SDRAM Status register (FMC\_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value

Bit 5 **BUSY**: Busy status

This bit defines the status of the SDRAM controller after a Command Mode request

0: SDRAM Controller is ready to accept a new request

1; SDRAM Controller is not ready to accept a new request

Bits 4:3 **MODES2[1:0]**: Status Mode for Bank 2

This bit defines the Status Mode of SDRAM Bank 2.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bits 2:1 **MODES1[1:0]**: Status Mode for Bank 1

This bit defines the Status Mode of SDRAM Bank 1.

00: Normal Mode

01: Self-refresh mode

10: Power-down mode

Bit 0 **RE**: Refresh error flag

0: No refresh error has been detected

1: A refresh error has been detected

An interrupt is generated if REIE = 1 and RE = 1

## 37.8 FMC register map

The following table summarizes the FMC registers.

**Table 298. FMC register map**

| Offset | Register  | 31       | 30          | 29 | 28 | 27          | 26 | 25 | 24          | 23 | 22 | 21           | 20 | 19       | 18          | 17          | 16          | 15          | 14     | 13     | 12          | 11      | 10      | 9       | 8        | 7        | 6         | 5         | 4         | 3         | 2     | 1     | 0 |

## 38 Debug support (DBG)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 38.1 Overview

The STM32F4xx are built around a Cortex®-M4 with FPU core, which contains hardware extensions for advanced debugging features. The debug extensions allow the core to be stopped either on a given instruction fetch (breakpoint), or on data access (watchpoint). When stopped, the core's internal state and the system's external state may be examined. Once examination is complete, the core and the system may be restored and program execution resumed.

The debug features are used by the debugger host when connecting to and debugging the STM32F4xx MCUs.

Two interfaces for debug are available:

- Serial wire
- JTAG debug port

**Figure 485. Block diagram of STM32 MCU and Cortex®-M4 with FPU-level debug support**

**Note:** The debug features embedded in the Cortex®-M4 with FPU core are a subset of the Arm® CoreSight Design Kit.

The Arm® Cortex®-M4 with FPU core provides integrated on-chip debug support. It is comprised of:

- SWJ-DP: Serial wire / JTAG debug port
- AHP-AP: AHB access port
- ITM: Instrumentation trace macrocell
- FPB: Flash patch breakpoint
- DWT: Data watchpoint trigger
- TPUI: Trace port unit interface (available on larger packages, where the corresponding pins are mapped)
- ETM: Embedded Trace Macrocell (available on larger packages, where the corresponding pins are mapped)

It also includes debug features dedicated to the STM32F4xx:

- Flexible debug pinout assignment
- MCU debug box (support for low-power modes, control over peripheral clocks, etc.)

*Note:* For further information on debug functionality supported by the Arm® Cortex®-M4 with FPU core, refer to the Cortex®-M4 with FPU -r0p1 Technical Reference Manual and to the CoreSight Design Kit-r0p1 TRM (see [Section 38.2](#)).

## 38.2 Reference Arm® documentation

- Arm® CoreSight Design Kit revision r0p1 Technical Reference Manual

## 38.3 SWJ debug port (serial wire and JTAG)

The core of the STM32F4xx integrates the Serial Wire / JTAG Debug Port (SWJ-DP). It is an Arm® standard CoreSight debug port that combines a JTAG-DP (5-pin) interface and a SW-DP (2-pin) interface.

- The JTAG Debug Port (JTAG-DP) provides a 5-pin standard JTAG interface to the AHP-AP port.
- The Serial Wire Debug Port (SW-DP) provides a 2-pin (clock + data) interface to the AHP-AP port.

In the SWJ-DP, the two JTAG pins of the SW-DP are multiplexed with some of the five JTAG pins of the JTAG-DP.

Figure 486. SWJ debug port

Figure 486 shows that the asynchronous TRACE output (TRACESWO) is multiplexed with TDO. This means that the asynchronous trace can only be used with SW-DP, not JTAG-DP.

### 38.3.1 Mechanism to select the JTAG-DP or the SW-DP

By default, the JTAG-Debug Port is active.

If the debugger host wants to switch to the SW-DP, it must provide a dedicated JTAG sequence on TMS/TCK (respectively mapped to SWDIO and SWCLK) which disables the JTAG-DP and enables the SW-DP. This way it is possible to activate the SWDP using only the SWCLK and SWDIO pins.

This sequence is:

1. Send more than 50 TCK cycles with TMS (SWDIO) = 1
2. Send the 16-bit sequence on TMS (SWDIO) = 0111100111100111 (MSB transmitted first)
3. Send more than 50 TCK cycles with TMS (SWDIO) = 1

## 38.4 Pinout and debug port pins

The STM32F4xx MCUs are available in various packages with different numbers of available pins. As a result, some functionality (ETM) related to pin availability may differ between packages.

### 38.4.1 SWJ debug port pins

Five pins are used as outputs from the STM32F4xx for the SWJ-DP as *alternate functions* of general-purpose I/Os. These pins are available on all packages.

**Table 299. SWJ debug port pins**

| SWJ-DP pin name | JTAG debug port |                          | SW debug port |                                    | Pin assignment |
|-----------------|-----------------|--------------------------|---------------|------------------------------------|----------------|
|                 | Type            | Description              | Type          | Debug assignment                   |                |
| JTMS/SWDIO      | I               | JTAG Test Mode Selection | IO            | Serial Wire Data Input/Output      | PA13           |
| JTCK/SWCLK      | I               | JTAG Test Clock          | I             | Serial Wire Clock                  | PA14           |
| JTDI            | I               | JTAG Test Data Input     | -             | -                                  | PA15           |
| JTDO/TRACESWO   | O               | JTAG Test Data Output    | -             | TRACESWO if async trace is enabled | PB3            |
| NJTRST          | I               | JTAG Test nReset         | -             | -                                  | PB4            |

### 38.4.2 Flexible SWJ-DP pin assignment

After RESET (SYSRESETn or PORESETn), all five pins used for the SWJ-DP are assigned as dedicated pins immediately usable by the debugger host (note that the trace outputs are not assigned except if explicitly programmed by the debugger host).

However, the STM32F4xx MCUs offers the possibility of disabling some or all of the SWJ-DP ports and so, of releasing the associated pins for general-purpose IO (GPIO) usage. For more details on how to disable SWJ-DP port pins, please refer to [Section 8.3.2: I/O pin multiplexer and mapping](#).

**Table 300. Flexible SWJ-DP pin assignment**

| Available debug ports                         | SWJ IO pin assigned |                     |             |            |              |
|-----------------------------------------------|---------------------|---------------------|-------------|------------|--------------|
|                                               | PA13 / JTMS / SWDIO | PA14 / JTCK / SWCLK | PA15 / JTDI | PB3 / JTDO | PB4 / NJTRST |
| Full SWJ (JTAG-DP + SW-DP) - Reset State      | X                   | X                   | X           | X          | X            |
| Full SWJ (JTAG-DP + SW-DP) but without NJTRST | X                   | X                   | X           | X          |              |
| JTAG-DP Disabled and SW-DP Enabled            | X                   | X                   |             |            |              |
| JTAG-DP Disabled and SW-DP Disabled           |                     |                     |             |            | Released     |

### 38.4.3 Internal pull-up and pull-down on JTAG pins

It is necessary to ensure that the JTAG input pins are not floating since they are directly connected to flip-flops to control the debug mode features. Special care must be taken with the SWCLK/TCK pin which is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled IO levels, the device embeds internal pull-ups and pull-downs on the JTAG input pins:

- NJTRST: Internal pull-up
- JTDI: Internal pull-up
- JTMS/SWDIO: Internal pull-up
- TCK/SWCLK: Internal pull-down

Once a JTAG IO is released by the user software, the GPIO controller takes control again. The reset states of the GPIO control registers put the I/Os in the equivalent state:

- NJTRST: AF input pull-up
- JTDI: AF input pull-up
- JTMS/SWDIO: AF input pull-up
- JTCK/SWCLK: AF input pull-down
- JTDO: AF output floating

The software can then use these I/Os as standard GPIOs.

*Note: The JTAG IEEE standard recommends to add pull-ups on TDI, TMS and nTRST but there is no special recommendation for TCK. However, for JTCK, the device needs an integrated pull-down.*

*Having embedded pull-ups and pull-downs removes the need to add external resistors.*

### 38.4.4 Using serial wire and releasing the unused debug pins as GPIOs

To use the serial wire DP to release some GPIOs, the user software must change the GPIO (PA15, PB3 and PB4) configuration mode in the GPIO\_MODER register. This releases PA15, PB3 and PB4 which now become available as GPIOs.

When debugging, the host performs the following actions:

- Under system reset, all SWJ pins are assigned (JTAG-DP + SW-DP).
- Under system reset, the debugger host sends the JTAG sequence to switch from the JTAG-DP to the SW-DP.
- Still under system reset, the debugger sets a breakpoint on vector reset.
- The system reset is released and the Core halts.
- All the debug communications from this point are done using the SW-DP. The other JTAG pins can then be reassigned as GPIOs by the user software.

*Note:* For user software designs, note that:

*To release the debug pins, remember that they are first configured either in input-pull-up (nTRST, TMS, TDI) or pull-down (TCK) or output tristate (TDO) for a certain duration after reset until the instant when the user software releases the pins.*

*When debug pins (JTAG or SW or TRACE) are mapped, changing the corresponding IO pin configuration in the IOPORT controller has no effect.*

## 38.5 STM32F4xx JTAG TAP connection

The STM32F4xx MCUs integrate two serially connected JTAG TAPs, the boundary scan TAP (IR is 5-bit wide) and the Cortex®-M4 with FPU TAP (IR is 4-bit wide).

To access the TAP of the Cortex®-M4 with FPU for debug purposes:

1. First, it is necessary to shift the BYPASS instruction of the boundary scan TAP.
2. Then, for each IR shift, the scan chain contains 9 bits (=5+4) and the unused TAP instruction must be shifted in using the BYPASS instruction.
3. For each data shift, the unused TAP, which is in BYPASS mode, adds 1 extra data bit in the data scan chain.

*Note:* **Important:** Once Serial-Wire is selected using the dedicated Arm® JTAG sequence, the boundary scan TAP is automatically disabled (JTMS forced high).

Figure 487. JTAG TAP connections

## 38.6 ID codes and locking mechanism

There are several ID codes inside the STM32F4xx MCUs. ST strongly recommends tools designers to lock their debuggers using the MCU DEVICE ID code located in the external PPB memory map at address 0xE0042000.

### 38.6.1 MCU device ID code

The STM32F4xx MCUs integrate an MCU ID code. This ID identifies the ST MCU part-number and the die revision. It is part of the DBG\_MCU component and is mapped on the external PPB bus (see [Section 38.16](#)). This code is accessible using the JTAG debug port (four to five pins) or the SW debug port (two pins) or by the user software. It is even accessible while the MCU is under system reset.

Only the DEV\_ID[11:0] must be used for identification by the debugger/programmer tools.

#### DBGMCU\_IDCODE

Address: 0xE004 2000

Only 32-bits access supported. Read-only.

Bits 31:16 **REV\_ID[15:0]** Revision identifier

This field indicates the revision of the device.

STM32F405xx/07xx and STM32F415xx/17xx devices:

0x1000 = Revision A

0x1001 = Revision Z

0x1003 = Revision 1

0x1007 = Revision 2

0x100F = Revision Y and 4

0x101F = Revision 5 and 6

STM32F42xxx and STM32F43xxx devices:

0x1000 = Revision A

0x1003 = Revision Y

0x1007 = Revision 1

0x2001 = Revision 3

0x2003 = Revision 4, 5 and B

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DEV\_ID[11:0]**: Device identifier (STM32F405xx/07xx and STM32F415xx/17xx)

The device ID is 0x413.

Bits 11:0 **DEV\_ID[11:0]**: Device identifier (STM32F42xxx and STM32F43xxx)

The device ID is 0x419

## 38.6.2 Boundary scan TAP

### JTAG ID code

The TAP of the STM32F4xx BSC (boundary scan) integrates a JTAG ID code equal to .

- 0x06413041 for STM32F405xx/07xx and STM32F415xx/17xx devices
- 0x06419041 for STM32F42xxx and STM32F43xxx devices

## 38.6.3 Cortex<sup>®</sup>-M4 with FPU TAP

The TAP of the Arm<sup>®</sup> Cortex<sup>®</sup>-M4 with FPU integrates a JTAG ID code. This ID code is the Arm<sup>®</sup> default one and has not been modified. This code is only accessible by the JTAG Debug Port, it is 0x4BA00477 (corresponds to Cortex<sup>®</sup>-M4 with FPU r0p1, see [Section 38.2](#)).

## 38.6.4 Cortex<sup>®</sup>-M4 with FPU JEDEC-106 ID code

The Arm<sup>®</sup> Cortex<sup>®</sup>-M4 with FPU integrates a JEDEC-106 ID code. It is located in the 4 KB ROM table mapped on the internal PPB bus at address 0xE00FF000\_0xE00FFFFF.

This code is accessible by the JTAG Debug Port (4 to 5 pins) or by the SW Debug Port (two pins) or by the user software.

## 38.7 JTAG debug port

A standard JTAG state machine is implemented with a 4-bit instruction register (IR) and five data registers (for full details, refer to the Cortex<sup>®</sup>-M4 with FPU r0p1 *Technical Reference Manual (TRM)*, for references, see [Section 38.2](#)).

**Table 301. JTAG debug port data registers**

| IR(3:0) | Data register       | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 38.8 SW debug port

### 38.8.1 SW protocol introduction

This synchronous serial protocol uses two pins:

- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to.

Bits are transferred LSB-first on the wire.

For SWDIO bidirectional management, the line must be pulled-up on the board (100 K $\Omega$  recommended by Arm®).

Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however this can be adjusted by configuring the SWCLK frequency.

### 38.8.2 SW protocol sequence

Each sequence consist of three phases:

1. Packet request (8 bits) transmitted by the host
2. Acknowledge response (3 bits) transmitted by the target
3. Data transfer phase (33 bits) transmitted by the host or the target

**Table 303. Packet request (8-bits)**

| Bit | Name   | Description                                                                      |
|-----|--------|----------------------------------------------------------------------------------|
| 0   | Start  | Must be “1”                                                                      |

| 4:3 | A[3:2] | Address field of the DP or AP registers (refer to <a href="#">Table 302</a> )    |
| 5   | Parity | Single bit parity of preceding bits                                              |
| 6   | Stop   | 0                                                                                |
| 7   | Park   | Not driven by the host. Must be read as “1” by the target because of the pull-up |

Refer to the Cortex®-M4 with FPU r0p1 *TRM* for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drive the line.

Table 304. ACK response (3 bits)

| Bit  | Name | Description                        |
|------|------|------------------------------------|
| 0..2 | ACK  | 001: FAULT<br>010: WAIT<br>100: OK |

The ACK Response must be followed by a turnaround time only if it is a READ transaction or if a WAIT or FAULT acknowledge has been received.

Table 305. DATA transfer (33 bits)

| Bit   | Name           | Description                       |
|-------|----------------|-----------------------------------|
| 0..31 | WDATA or RDATA | Write or Read data                |
| 32    | Parity         | Single parity of the 32 data bits |

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

### 38.8.3 SW-DP state machine (reset, idle states, ID code)

The State Machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard. This ID code is the default Arm<sup>®</sup> one and is set to **0x2BA01477** (corresponding to Cortex<sup>®</sup>-M4 with FPU r0p1).

*Note:*

*Note that the SW-DP state machine is inactive until the target reads this ID code.*

- The SW-DP state machine is in RESET STATE either after power-on reset, or after the DP has switched from JTAG to SWD or after the line is high for more than 50 cycles
- The SW-DP state machine is in IDLE STATE if the line is low for at least two cycles after RESET state.
- After RESET state, it is **mandatory** to first enter into an IDLE state AND to perform a READ access of the DP-SW ID CODE register. Otherwise, the target issues a FAULT acknowledge response on another transactions.

Further details of the SW-DP state machine can be found in the Cortex<sup>®</sup>-M4 with FPU r0p1 *TRM* and the *CoreSight Design Kit r0p1 TRM*.

### 38.8.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is returned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result.  
The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP or AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the target acknowledge response is "WAIT". With the exception of

IDCODE read or CTRL/STAT read or ABORT write which are accepted even if the write buffer is full.

- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles must be applied while driving the line low (IDLE state). This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it fails.

### 38.8.5 SW-DP registers

Access to these registers are initiated when APnDP=0

**Table 306. SW-DP registers**

| A[3:2] | R/W        | CTRLSEL bit of SELECT register | Register     | Notes                                                                                                                                                                                                                                                                                            |
|--------|------------|--------------------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 00     | Read       | -                              | IDCODE       | The manufacturer code is not set to ST code. <b>0x2BA01477</b> (identifies the SW-DP)                                                                                                                                                                                                            |
| 00     | Write      | -                              | ABORT        | -                                                                                                                                                                                                                                                                                                |
| 01     | Read/Write | 0                              | DP-CTRL/STAT | Purpose is to: <ul style="list-style-type: none"> <li>request a system or debug power-up</li> <li>configure the transfer operation for AP accesses</li> <li>control the pushed compare and pushed verify operations.</li> <li>read some status flags (overrun, power-up acknowledges)</li> </ul> |
| 01     | Read/Write | 1                              | WIRE CONTROL | Purpose is to configure the physical serial port protocol (like the duration of the turnaround time)                                                                                                                                                                                             |
| 10     | Read       | -                              | READ RESEND  | Enables recovery of the read data from a corrupted debugger transfer, without repeating the original AP transfer.                                                                                                                                                                                |
| 10     | Write      | -                              | SELECT       | The purpose is to select the current access port and the active 4-words register window                                                                                                                                                                                                          |
| 11     | Read/Write | -                              | READ BUFFER  | This read buffer is useful because AP accesses are posted (the result of a read AP request is available on the next AP transaction). This read buffer captures data from the AP, presented as the result of a previous read, without initiating a new transaction                                |

### 38.8.6 SW-AP registers

Access to these registers are initiated when APnDP=1

There are many AP registers (see AHB-AP) addressed as the combination of:

- The shifted value A[3:2]
- The current value of the DP SELECT register

## 38.9 AHB-AP (AHB access port) - valid for both JTAG-DP and SW-DP

### Features:

- System access is independent of the processor status.
- Either SW-DP or JTAG-DP accesses AHB-AP.
- The AHB-AP is an AHB master into the Bus Matrix. Consequently, it can access all the data buses (Dcode Bus, System Bus, internal and external PPB bus) but the ICode bus.
- Bitband transactions are supported.
- AHB-AP transactions bypass the FPB.

The address of the 32-bits AHB-AP registers are 6-bits wide (up to 64 words or 256 bytes) and consists of:

- c) Bits [7:4] = the bits [7:4] APBANKSEL of the DP SELECT register
- d) Bits [3:2] = the 2 address bits of A[3:2] of the 35-bit packet request for SW-DP.

The AHB-AP of the Cortex<sup>®</sup>-M4 with FPU includes 9 x 32-bits registers:

**Table 307. Cortex<sup>®</sup>-M4 with FPU AHB-AP registers**

| Address offset | Register name                  | Notes                                                                                                                         |
|----------------|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 0x00           | AHB-AP Control and Status Word | Configures and controls transfers through the AHB interface (size, hprot, status on current transfer, address increment type) |
| 0x04           | AHB-AP Transfer Address        | -                                                                                                                             |
| 0x0C           | AHB-AP Data Read/Write         | -                                                                                                                             |
| 0x10           | AHB-AP Banked Data 0           | Directly maps the 4 aligned data words without rewriting the Transfer Address register.                                       |
| 0x14           | AHB-AP Banked Data 1           |                                                                                                                               |
| 0x18           | AHB-AP Banked Data 2           |                                                                                                                               |
| 0x1C           | AHB-AP Banked Data 3           |                                                                                                                               |
| 0xF8           | AHB-AP Debug ROM Address       | Base Address of the debug interface                                                                                           |
| 0xFC           | AHB-AP ID register             | -                                                                                                                             |

Refer to the Cortex<sup>®</sup>-M4 with FPU *r0p1 TRM* for further details.

## 38.10 Core debug

Core debug is accessed through the core debug registers. Debug access to these registers is by means of the *Advanced High-performance Bus* (AHB-AP) port. The processor can access these registers directly over the internal *Private Peripheral Bus* (PPB).

It consists of 4 registers:

**Table 308. Core debug registers**

| Register | Description                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DHCSR    | The 32-bit Debug Halting Control and Status register<br>This provides status information about the state of the processor enable core debug halt and step the processor                                |
| DCRSR    | The 17-bit Debug Core register Selector register:<br>This selects the processor register to transfer data to or from.                                                                                  |
| DCRDR    | The 32-bit Debug Core register Data register:<br>This holds data for reading and writing registers to and from the processor selected by the DCRSR (Selector) register.                                |
| DEMCR    | The 32-bit Debug Exception and Monitor Control register:<br>This provides Vector Catching and Debug Monitor Control. This register contains a bit named <b>TRCENA</b> which enable the use of a TRACE. |

*Note:* **Important:** these registers are not reset by a system reset. They are only reset by a power-on reset.

Refer to the Cortex®-M4 with FPU r0p1 TRM for further details.

To Halt on reset, it is necessary to:

- enable the bit0 (VC\_CORRESET) of the Debug and Exception Monitor Control register
- enable the bit0 (C\_DEBUGEN) of the Debug Halting Control and Status register.

## 38.11 Capability of the debugger host to connect under system reset

The reset system of the STM32F4xx MCU comprises the following reset sources:

- POR (power-on reset) which asserts a RESET at each power-up.
- Internal watchdog reset
- Software reset
- External reset

The Cortex<sup>®</sup>-M4 with FPU differentiates the reset of the debug part (generally PORRESETn) and the other one (SYSRESETn)

This way, it is possible for the debugger to connect under System Reset, programming the Core Debug registers to halt the core when fetching the reset vector. Then the host can release the system reset and the core immediately halts without having executed any instructions. In addition, it is possible to program any debug features under System Reset.

*Note: It is highly recommended for the debugger host to connect (set a breakpoint in the reset vector) under system reset.*

## 38.12 FPB (Flash patch breakpoint)

The FPB unit:

- implements hardware breakpoints
- patches code and data from code space to system space. This feature gives the possibility to correct software bugs located in the Code Memory Space.

The use of a Software Patch or a Hardware Breakpoint is exclusive.

The FPB consists of:

- 2 literal comparators for matching against literal loads from Code Space and remapping to a corresponding area in the System Space.
- 6 instruction comparators for matching against instruction fetches from Code Space. They can be used either to remap to a corresponding area in the System Space or to generate a Breakpoint Instruction to the core.

## 38.13 DWT (data watchpoint trigger)

The DWT unit consists of four comparators. They are configurable as:

- a hardware watchpoint or
- a trigger to an ETM or
- a PC sampler or
- a data address sampler

The DWT also provides some means to give some profiling informations. For this, some counters are accessible to give the number of:

- Clock cycle
- Folded instructions
- Load store unit (LSU) operations
- Sleep cycles
- CPI (clock per instructions)
- Interrupt overhead

## 38.14 ITM (instrumentation trace macrocell)

### 38.14.1 General description

The ITM is an application-driven trace source that supports *printf* style debugging to trace *Operating System* (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets which can be generated as:

- **Software trace.** Software can write directly to the ITM stimulus registers to emit packets.
- **Hardware trace.** The DWT generates these packets, and the ITM emits them.
- **Time stamping.** Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex<sup>®</sup>-M4 with FPU clock or the bit clock rate of the *Serial Wire Viewer* (SWV) output clocks the counter.

The packets emitted by the ITM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to TPIU) and then output the complete packets sequence to the debugger host.

The bit TRCEN of the Debug Exception and Monitor Control register must be enabled before programming or using the ITM.

### 38.14.2 Time stamp packets, synchronization and overflow packets

Time stamp packets encode time stamp information, generic control and synchronization. It uses a 21-bit timestamp counter (with possible prescalers) which is reset at each time stamp packet emission. This counter can be either clocked by the CPU clock or the SWV clock.

A synchronization packet consists of 6 bytes equal to 0x80\_00\_00\_00\_00\_00 which is emitted to the TPIU as 00 00 00 00 00 80 (LSB emitted first).

A synchronization packet is a timestamp packet control. It is emitted at each DWT trigger.

For this, the DWT must be configured to trigger the ITM: the bit CYCCNTENA (bit0) of the DWT Control register must be set. In addition, the bit2 (SYNCENA) of the ITM Trace Control register must be set.

*Note: If the SYNENA bit is not set, the DWT generates Synchronization triggers to the TPIU which sends only TPIU synchronization packets and not ITM synchronization packets.*

An overflow packet consists is a special timestamp packets which indicates that data has been written but the FIFO was full.

**Table 309. Main ITM registers**

| Address                | Register                     | Details                                                                                                                                                   |
|------------------------|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

| @E0000E00              | ITM trace enable             | Each bit enables the corresponding Stimulus port to generate trace.                                                                                       |
| @E0000000-<br>E000007C | Stimulus port registers 0-31 | Write the 32-bits data on the selected Stimulus Port (32 available) to be traced out.                                                                     |

### Example of configuration

To output a simple value to the TPIU:

- Configure the TPIU and assign TRACE I/Os by configuring the DBGMCU\_CR (refer to [Section 38.17.2](#) and [Section 38.16.3](#))
- Write 0xC5ACCE55 to the ITM Lock Access register to unlock the write access to the ITM registers
- Write 0x00010005 to the ITM Trace Control register to enable the ITM with Sync enabled and an ATB ID different from 0x00
- Write 0x1 to the ITM Trace Enable register to enable the Stimulus Port 0
- Write 0x1 to the ITM Trace Privilege register to unmask stimulus ports 7:0
- Write the value to output in the Stimulus Port register 0: this can be done by software (using a printf function)

## 38.15 ETM (Embedded Trace Macrocell™)

### 38.15.1 ETM general description

The ETM enables the reconstruction of program execution. Data are traced using the Data Watchpoint and Trace (DWT) component or the Instruction Trace Macrocell (ITM) whereas instructions are traced using the Embedded Trace Macrocell (ETM).

The ETM transmits information as packets and is triggered by embedded resources. These resources must be programmed independently and the trigger source is selected using the Trigger Event register (0xE0041008). An event could be a simple event (address match from an address comparator) or a logic equation between 2 events. The trigger source is one of the fourth comparators of the DWT module. The following events can be monitored:

- Clock cycle matching
- Data address matching

For more informations on the trigger resources refer to [Section 38.13](#).

The packets transmitted by the ETM are output to the TPIU (Trace Port Interface Unit). The formatter of the TPIU adds some extra packets (refer to [Section 38.17](#)) and then outputs the complete packet sequence to the debugger host.

### 38.15.2 ETM signal protocol and packet types

This part is described in the chapter 7 ETMv3 Signal Protocol of the Arm® IHI 0014N document.

### 38.15.3 Main ETM registers

For more information on registers refer to the chapter 3 of the Arm® IHI 0014N specification.

**Table 310. Main ETM registers**

| Address    | Register                 | Details                                                                                                |
|------------|--------------------------|--------------------------------------------------------------------------------------------------------|
| 0xE0041FB0 | ETM Lock Access          | Write 0xC5ACCE55 to unlock the write access to the other ETM registers.                                |
| 0xE0041000 | ETM Control              | This register controls the general operation of the ETM, for instance how tracing is enabled.          |
| 0xE0041010 | ETM Status               | This register provides information about the current status of the trace and trigger logic.            |
| 0xE0041008 | ETM Trigger Event        | This register defines the event that controls trigger.                                                 |
| 0xE004101C | ETM Trace Enable Control | This register defines which comparator is selected.                                                    |
| 0xE0041020 | ETM Trace Enable Event   | This register defines the trace enabling event.                                                        |
| 0xE0041024 | ETM Trace Start/Stop     | This register defines the traces used by the trigger source to start and stop the trace, respectively. |

### 38.15.4 ETM configuration example

To output a simple value to the TPIU:

- Configure the TPIU and enable the I/O\_TRACEN to assign TRACE I/Os in the STM32F4xx debug configuration register.
- Write 0xC5AC CE55 to the ETM Lock Access register to unlock the write access to the ITM registers
- Write 0x0000 1D1E to the ETM control register (configure the trace)
- Write 0x0000 406F to the ETM Trigger Event register (define the trigger event)
- Write 0x0000 006F to the ETM Trace Enable Event register (define an event to start/stop)
- Write 0x0200 0000x0000 0001 to the ETM Trace Start/stop register (enable the trace)
- Write 0x0000191E to the ETM Control register (end of configuration)

## 38.16 MCU debug component (DBGMCU)

The MCU debug component helps the debugger provide support for:

- Low-power modes
- Clock control for timers, watchdog, I2C and bxCAN during a breakpoint
- Control of the trace pins assignment

### 38.16.1 Debug support for low-power modes

To enter low-power mode, the instruction WFI or WFE must be executed.

The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU.

The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug software in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode, DBG\_SLEEP bit of DBGMCU\_CR register must be previously set by the debugger. This feeds HCLK with the same clock that is provided to FCLK (system clock previously configured by the software).
- In Stop mode, the bit DBG\_STOP must be previously set by the debugger. This enables the internal RC oscillator clock to feed FCLK and HCLK in STOP mode.

### 38.16.2 Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C

During a breakpoint, it is necessary to choose how the counter of timers and watchdog must behave:

- They can continue to count inside a breakpoint. This is usually required when a PWM is controlling a motor, for example.
- They can stop to count inside a breakpoint. This is required for watchdog purposes.

For the bxCAN, the user can choose to block the update of the receive register during a breakpoint.

For the I<sup>2</sup>C, the user can choose to block the SMBUS timeout during a breakpoint.

For timers having complementary outputs, when the counter is stopped (DBG\_TIMx\_STOP = 1), the outputs are disabled (as if the MOE bit was reset) for safety purposes.

### 38.16.3 Debug MCU configuration register

This register allows the configuration of the MCU under DEBUG. This concerns:

- Low-power mode support
- Timer and watchdog counter support
- bxCAN communication support
- Trace pin assignment

This DBGMCU\_CR is mapped on the External PPB bus at address 0xE0042004

It is asynchronously reset by the PORESET (and not the system reset). It can be written by the debugger under system reset.

If the debugger host does not support these features, it is still possible for the user software to write to these registers.

#### DBGMCU\_CR register

Address: 0xE004 2004

Only 32-bit access supported

POR Reset: 0x0000 0000 (not reset by system reset)

|          |    |    |    |    |    |    |    |                  |    |            |          |    |             |          |           |
|----------|----|----|----|----|----|----|----|------------------|----|------------|----------|----|-------------|----------|-----------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23               | 22 | 21         | 20       | 19 | 18          | 17       | 16        |
| Reserved |    |    |    |    |    |    |    |                  |    |            |          |    |             |          |           |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7                | 6  | 5          | 4        | 3  | 2           | 1        | 0         |
| Reserved |    |    |    |    |    |    |    | TRACE_MODE [1:0] |    | TRACE_IOEN | Reserved |    | DBG_STANDBY | DBG_STOP | DBG_SLEEP |
|          |    |    |    |    |    |    |    | rw               | rw | rw         |          |    | rw          | rw       | rw        |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:5 **TRACE\_MODE[1:0] and TRACE\_IOEN**: Trace pin assignment control

- With TRACE\_IOEN=0:
  - TRACE\_MODE=xx: TRACE pins not assigned (default state)
- With TRACE\_IOEN=1:
  - TRACE\_MODE=00: TRACE pin assignment for Asynchronous mode
  - TRACE\_MODE=01: TRACE pin assignment for Synchronous mode with a TRACEDATA size of 1
  - TRACE\_MODE=10: TRACE pin assignment for Synchronous mode with a TRACEDATA size of 2
  - TRACE\_MODE=11: TRACE pin assignment for Synchronous mode with a TRACEDATA size of 4

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **DBG\_STANDBY**: Debug Standby mode

0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered.

From software point of view, exiting from Standby is identical than fetching reset vector (except a few status bit indicated that the MCU is resuming from Standby)

1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU generate a system reset during Standby mode so that exiting from Standby is identical than fetching from reset

Bit 1 **DBG\_STOP**: Debug Stop mode

0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI)). Consequently, the software must reprogram the clock controller to enable the PLL, the Xtal, etc.

1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are provided by the internal RC oscillator which remains active in STOP mode. When exiting STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. (in the same way it would do in case of DBG\_STOP=0)

Bit 0 **DBG\_SLEEP**: Debug Sleep mode

0: (FCLK=On, HCLK=Off) In Sleep mode, FCLK is clocked by the system clock as previously configured by the software while HCLK is disabled.

In Sleep mode, the clock controller configuration is not reset and remains in the previously programmed state. Consequently, when exiting from Sleep mode, the software does not need to reconfigure the clock controller.

1: (FCLK=On, HCLK=On) In this case, when entering Sleep mode, HCLK is fed by the same clock that is provided to FCLK (system clock as previously configured by the software).

### 38.16.4 Debug MCU APB1 freeze register (DBGMCU\_APB1\_FZ)

The DBGMCU\_APB1\_FZ register is used to configure the MCU under Debug. It concerns APB1 peripherals. It is mapped on the external PPB bus at address 0xE004 2008.

The register is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address : 0xE004 2008

Only 32-bits access are supported.

Power-on reset (POR): 0x0000 0000 (not reset by system reset)

|          |    |    |    |               |               |               |          |                        |                        |                        |               |               |               |               |               |

|          |    |    |    |               |               |               |          | DBG_TIM2_STOP          |                        |                        |               |               |               |               |               |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DBG\_CAN2\_STOP**: Debug CAN2 stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The CAN2 receive registers are frozen

Bit 25 **DBG\_CAN1\_STOP**: Debug CAN2 stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The CAN2 receive registers are frozen

Bit 24 Reserved, must be kept at reset value.

Bit 23 **DBG\_I2C3\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bit 22 **DBG\_I2C2\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bit 21 **DBG\_I2C1\_SMBUS\_TIMEOUT**: SMBUS timeout mode stopped when Core is halted

- 0: Same behavior as in normal mode
- 1: The SMBUS timeout is frozen

Bit 20:13 Reserved, must be kept at reset value.

Bit 12 **DBG\_IWDG\_STOP**: Debug independent watchdog stopped when core is halted  
 0: The independent watchdog counter clock continues even if the core is halted  
 1: The independent watchdog counter clock is stopped when the core is halted

Bit 11 **DBG\_WWDG\_STOP**: Debug Window Watchdog stopped when Core is halted  
 0: The window watchdog counter clock continues even if the core is halted  
 1: The window watchdog counter clock is stopped when the core is halted

Bit 10 **DBG\_RTC\_STOP**: RTC stopped when Core is halted  
 0: The RTC counter clock continues even if the core is halted  
 1: The RTC counter clock is stopped when the core is halted

Bit 9 Reserved, must be kept at reset value.

Bits 8:0 **DBG\_TIMx\_STOP**: TIMx counter stopped when core is halted (x=2..7, 12..14)  
 0: The clock of the involved timer counter is fed even if the core is halted  
 1: The clock of the involved timer counter is stopped and the outputs are disabled when the core is halted

### 38.16.5 Debug MCU APB2 Freeze register (DBGMCU\_APB2\_FZ)

The DBGMCU\_APB2\_FZ register is used to configure the MCU under Debug. It concerns APB2 peripherals.

This register is mapped on the external PPB bus at address 0xE004 200C

It is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address: 0xE004 200C

Only 32-bit access is supported.

POR: 0x0000 0000 (not reset by system reset)

|          |    |    |    |    |    |    |    |    |    |    |    |    |                |                |               |

| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | DBG_TIM8_STOP  | DBG_TIM1_STOP  |               |
|          |    |    |    |    |    |    |    |    |    |    |    |    | rw             | rw             |               |

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **DBG\_TIMx\_STOP**: TIMx counter stopped when core is halted (x=9..11)  
 0: The clock of the involved timer counter is fed even if the core is halted  
 1: The clock of the involved timer counter is stopped and the outputs are disabled when the core is halted

Bits 15: Reserved, must be kept at reset value.

Bit 1 **DBG\_TIM8\_STOP**: TIM8 counter stopped when core is halted

0: The clock of the involved timer counter is fed even if the core is halted

1: The clock of the involved timer counter is stopped and the outputs are disabled when the core is halted

Bit 0 **DBG\_TIM1\_STOP**: TIM1 counter stopped when core is halted

0: The clock of the involved timer counter is fed even if the core is halted

1: The clock of the involved timer counter is stopped and the outputs are disabled when the core is halted

## 38.17 TPIU (trace port interface unit)

### 38.17.1 Introduction

The TPIU acts as a bridge between the on-chip trace data from the ITM and the ETM.

The output data stream encapsulates the trace source ID, that is then captured by a *trace port analyzer* (TPA).

The core embeds a simple TPIU, especially designed for low-cost debug (consisting of a special version of the CoreSight TPIU).

**Figure 488. TPIU block diagram**

### 38.17.2 TRACE pin assignment

- **Asynchronous mode**  
The asynchronous mode requires 1 extra pin and is available on all packages. It is only available if using Serial Wire mode (not in JTAG mode).

**Table 311. Asynchronous TRACE pin assignment**

| TPUI pin name | Trace synchronous mode |                         | STM32F4xx pin assignment |
|---------------|------------------------|-------------------------|--------------------------|
|               | Type                   | Description             |                          |
| TRACESWO      | O                      | TRACE Async Data Output | PB3                      |

- **Synchronous mode**  
The synchronous mode requires from 2 to 6 extra pins depending on the data trace size and is only available in the larger packages. In addition it is available in JTAG mode and in Serial Wire mode and provides better bandwidth output capabilities than asynchronous trace.

**Table 312. Synchronous TRACE pin assignment**

| TPUI pin name | Trace synchronous mode |                                              | STM32F4xxpin assignment |
|---------------|------------------------|----------------------------------------------|-------------------------|
|               | Type                   | Description                                  |                         |
| TRACECK       | O                      | TRACE Clock                                  | PE2                     |
| TRACED[3:0]   | O                      | TRACE Sync Data Outputs<br>Can be 1, 2 or 4. | PE[6:3]                 |

#### TPUI TRACE pin assignment

By default, these pins are NOT assigned. They can be assigned by setting the TRACE\_IOEN and TRACE\_MODE bits in the **MCU Debug component configuration register**. This configuration has to be done by the debugger host.

In addition, the number of pins to assign depends on the trace configuration (asynchronous or synchronous).

- **Asynchronous mode:** 1 extra pin is needed
- **Synchronous mode:** from 2 to 5 extra pins are needed depending on the size of the data trace port register (1, 2 or 4):
  - TRACECK
  - TRACED(0) if port size is configured to 1, 2 or 4
  - TRACED(1) if port size is configured to 2 or 4
  - TRACED(2) if port size is configured to 4
  - TRACED(3) if port size is configured to 4

To assign the TRACE pin, the debugger host must program the bits TRACE\_IOEN and TRACE\_MODE[1:0] of the Debug MCU configuration register (DBGMCU\_CR). By default the TRACE pins are not assigned.

This register is mapped on the external PPB and is reset by the PORESET (and not by the SYSTEM reset). It can be written by the debugger under SYSTEM reset.

Table 313. Flexible TRACE pin assignment

| DBGMCU_CR register |                  | Pins assigned for:       | TRACE IO pin assigned   |              |                 |                           |                 |                 |
|--------------------|------------------|--------------------------|-------------------------|--------------|-----------------|---------------------------|-----------------|-----------------|
| TRACE_IOEN         | TRACE_MODE [1:0] |                          | PB3 /JTDO/ TRACESWO     | PE2/ TRACECK | PE3 / TRACED[0] | PE4 / TRACED[1]           | PE5 / TRACED[2] | PE6 / TRACED[3] |
| 0                  | XX               | No Trace (default state) | Released <sup>(1)</sup> | -            |                 |                           |                 |                 |
| 1                  | 00               | Asynchronous Trace       | TRACESWO                | -            | -               | Released (usable as GPIO) |                 |                 |
| 1                  | 01               | Synchronous Trace 1 bit  | Released <sup>(1)</sup> | TRACECK      | TRACED[0]       | -                         | -               | -               |
| 1                  | 10               | Synchronous Trace 2 bit  |                         | TRACECK      | TRACED[0]       | TRACED[1]                 | -               | -               |
| 1                  | 11               | Synchronous Trace 4 bit  |                         | TRACECK      | TRACED[0]       | TRACED[1]                 | TRACED[2]       | TRACED[3]       |

1. When Serial Wire mode is used, it is released. But when JTAG is used, it is assigned to JTDO.

**Note:** By default, the TRACECLKIN input clock of the TPIU is tied to GND. It is assigned to HCLK two clock cycles after the bit TRACE\_IOEN has been set.

The debugger must then program the Trace Mode by writing the PROTOCOL[1:0] bits in the SPP\_R (Selected Pin Protocol) register of the TPIU.

- PROTOCOL=00: Trace Port Mode (synchronous)
- PROTOCOL=01 or 10: Serial Wire (Manchester or NRZ) Mode (asynchronous mode). Default state is 01

It then also configures the TRACE port size by writing the bits [3:0] in the CPSPS\_R (Current Sync Port Size register) of the TPIU:

- 0x1 for 1 pin (default state)
- 0x2 for 2 pins
- 0x8 for 4 pins

### 38.17.3 TPUI formatter

The formatter protocol outputs data in 16-byte frames:

- seven bytes of data
- eight bytes of mixed-use bytes consisting of:
  - 1 bit (LSB) to indicate it is a DATA byte ('0') or an ID byte ('1').
  - 7 bits (MSB) which can be data or change of source ID trace.
- one byte of auxiliary bits where each bit corresponds to one of the eight mixed-use bytes:
  - if the corresponding byte was a data, this bit gives bit0 of the data.
  - if the corresponding byte was an ID change, this bit indicates when that ID change takes effect.

*Note: Refer to the Arm® CoreSight Architecture Specification v1.0 (Arm® IHI 0029B) for further information*

### 38.17.4 TPUI frame synchronization packets

The TPUI can generate two types of synchronization packets:

- The Frame Synchronization packet (or Full Word Synchronization packet)  
It consists of the word: 0x7F\_FF\_FF\_FF (LSB emitted first). This sequence can not occur at any other time provided that the ID source code 0x7F has not been used.  
It is output periodically **between** frames.  
In continuous mode, the TPA must discard all these frames once a synchronization frame has been found.
- The Half-Word Synchronization packet  
It consists of the half word: 0x7F\_FF (LSB emitted first).  
It is output periodically **between or within** frames.  
These packets are only generated in continuous mode and enable the TPA to detect that the TRACE port is in IDLE mode (no TRACE to be captured). When detected by the TPA, it must be discarded.

### 38.17.5 Transmission of the synchronization frame packet

There is no Synchronization Counter register implemented in the TPIU of the core. Consequently, the synchronization trigger can only be generated by the **DWT**. Refer to the registers DWT Control register (bits SYNCTAP[11:10]) and the DWT Current PC Sampler Cycle Count register.

The TPUI Frame synchronization packet (0x7F\_FF\_FF\_FF) is emitted:

- after each TPIU reset release. This reset is synchronously released with the rising edge of the TRACECLKIN clock. This means that this packet is transmitted when the TRACE\_IOEN bit in the DBGMCU\_CFG register is set. In this case, the word 0x7F\_FF\_FF\_FF is not followed by any formatted packet.
- at each DWT trigger (assuming DWT has been previously configured). Two cases occur:
  - If the bit SYNENA of the ITM is reset, only the word 0x7F\_FF\_FF\_FF is emitted without any formatted stream which follows.
  - If the bit SYNENA of the ITM is set, then the ITM synchronization packets follow (0x80\_00\_00\_00\_00\_00), formatted by the TPUI (trace source ID added).

### 38.17.6 Synchronous mode

The trace data output size can be configured to 4, 2 or 1 pin: TRACED(3:0)

The output clock is output to the debugger (TRACECK)

Here, TRACECLKIN is driven internally and is connected to HCLK only when TRACE is used.

*Note: In this synchronous mode, it is not required to provide a stable clock frequency.*

The TRACE I/Os (including TRACECK) are driven by the rising edge of TRACCLKIN (equal to HCLK). Consequently, the output frequency of TRACECK is equal to HCLK/2.

### 38.17.7 Asynchronous mode

This is a low cost alternative to output the trace using only 1 pin: this is the asynchronous output pin TRACESWO. Obviously there is a limited bandwidth.

TRACESWO is multiplexed with JTDO when using the SW-DP pin. This way, this functionality is available in all STM32F4xx packages.

This asynchronous mode requires a constant frequency for TRACECLKIN. For the standard UART (NRZ) capture mechanism, 5% accuracy is needed. The Manchester encoded version is tolerant up to 10%.

### 38.17.8 TRACECLKIN connection inside the STM32F4xx

In the STM32F4xx, this TRACECLKIN input is internally connected to HCLK. This means that when in asynchronous trace mode, the application is restricted to use to time frames where the CPU frequency is stable.

**Note:** ***Important:** when using asynchronous trace: it is important to be aware that:*

*The default clock of the STM32F4xx MCUs is the internal RC oscillator. Its frequency under reset is different from the one after reset release. This is because the RC calibration is the default one under system reset and is updated at each system reset release.*

*Consequently, the trace port analyzer (TPA) must not enable the trace (with the TRACE\_IOEN bit) under system reset, because a Synchronization Frame Packet is issued with a different bit time than trace packets which are transmitted after reset release.*

### 38.17.9 TPIU registers

The TPIU APB registers can be read and written only if the bit TRCENA of the Debug Exception and Monitor Control register (DEMCR) is set. Otherwise, the registers are read as zero (the output of this bit enables the PCLK of the TPIU).

**Table 314. Important TPIU registers**

| Address    | Register              | Description                                                                                                                                                                                                                             |
|------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0xE0040004 | Current port size     | Allows the trace port size to be selected:<br>Bit 0: Port size = 1<br>Bit 1: Port size = 2<br>Bit 2: Port size = 3, not supported<br>Bit 3: Port Size = 4<br>Only 1 bit must be set. By default, the port size is one bit. (0x00000001) |
| 0xE00400F0 | Selected pin protocol | Allows the Trace Port Protocol to be selected:<br>Bit1:0=<br>00: Sync Trace Port Mode<br>01: Serial Wire Output - manchester (default value)<br>10: Serial Wire Output - NRZ<br>11: reserved                                            |

Table 314. Important TPIU registers (continued)

| Address    | Register                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0xE0040304 | Formatter and flush control | <p>Bits 31-9 = always '0<br/>           Bit 8 = TrgIn = always '1 to indicate that triggers are indicated<br/>           Bits 7-4 = always 0<br/>           Bits 3-2 = always 0<br/>           Bit 1 = EnFCont. In Sync Trace mode (Select_Pin_Protocol register bit1:0=00), this bit is forced to '1: the formatter is automatically enabled in continuous mode. In asynchronous mode (Select_Pin_Protocol register bit1:0 &lt;&gt; 00), this bit can be written to activate or not the formatter.<br/>           Bit 0 = always 0</p> <p>The resulting default value is 0x102</p> <p><b>Note:</b> In synchronous mode, because the TRACECTL pin is not mapped outside the chip, the formatter is always enabled in continuous mode -this way the formatter inserts some control packets to identify the source of the trace packets).</p> |
| 0xE0040300 | Formatter and flush status  | Not used in Cortex®-M4 with FPU, always read as 0x00000008                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 38.17.10 Example of configuration

- Set the bit TRCENA in the Debug Exception and Monitor Control register (DEMCR)
- Write the TPIU Current Port Size register to the desired value (default is 0x1 for a 1-bit port size)
- Write TPIU Formatter and Flush Control register to 0x102 (default value)
- Write the TPIU Select Pin Protocol to select the sync or async mode. Example: 0x2 for async NRZ mode (UART like)
- Write the DBGMCU control register to 0x20 (bit IO\_TRACEN) to assign TRACE I/Os for async mode. A TPIU Sync packet is emitted at this time (FF\_FF\_FF\_7F)
- Configure the ITM and write the ITM Stimulus register to output a value

## 38.18 DBG register map

The following table summarizes the Debug registers.

**Table 315. DBG register map and reset values**

| Addr.          | Register                   | 31       | 30 | 29 | 28 | 27            | 26 | 25            | 24 | 23       | 22 | 21                     | 20 | 19                     | 18 | 17                     | 16 | 15            | 14 | 13            | 12 | 11                     | 10 | 9        | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |   |

1. The reset value is product dependent. For more information, refer to [Section 38.6.1: MCU device ID code](#).

## 39 Device electronic signature

The electronic signature is stored in the Flash memory area. It can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32F4xx microcontrollers.

### 39.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

**Base address: 0x1FFF 7A10**

Address offset: 0x00

Read only = 0xFFFF XXXX where X is factory-programmed

Bits 31:0 **UID(31:0)**: X and Y coordinates on the wafer

Address offset: 0x04

Read only = 0xFFFF XXXX where X is factory-programmed

Bits 31:8 **UID(63:40):** LOT\_NUM[23:0]  
 Lot number (ASCII encoded).

Bits 7:0 **UID(39:32):** WAF\_NUM[7:0]  
 Wafer number (ASCII encoded).

Address offset: 0x08

Read only = 0xFFFF XXXX where X is factory-programmed

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| UID(95:80) |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| UID(79:64) |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **UID(95:64):** LOT\_NUM[55:24]  
 Lot number (ASCII encoded).

## 39.2 Flash size

Base address: 0x1FFF 7A22

Address offset: 0x00

Read only = 0xFFFF where X is factory-programmed

|        |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 15     | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| F_SIZE |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| r      | r  | r  | r  | r  | r  | r | r | r | r | r | r | r | r | r | r |

Bits 15:0 **F\_ID(15:0):** Flash memory size  
 This bitfield indicates the size of the device Flash memory expressed in Kbytes.  
 As an example, 0x0400 corresponds to 1024 Kbytes.

## 40 Important security notice

The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST's customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture ([www.psacertified.org](http://www.psacertified.org)) and/or Security Evaluation standard for IoT Platforms ([www.trustcb.com](http://www.trustcb.com)). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on [www.st.com](http://www.st.com) for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.
- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.
- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.
- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.
- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.

## 41 Revision history

| 15-Sep-2011 | 1       | Initial release.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 19-Oct-2012 | 2       | <p>Updated reference documents and added Table 1: Applicable products on cover page.</p> <p><b>MEMORY:</b><br/>Updated Section 2: Memory and bus architecture.</p> <p><b>PWR:</b><br/>Updated VDDA and VREF+ decoupling capacitor in Figure 7: Power supply overview.<br/>VOSRDY bit changed to read-only in Section 5.4.3: PWR power control/status register (PWR_CSR).<br/>Removed VDDA in Section 5.2.3: Programmable voltage detector (PVD) and remove VDDA in PVDO bit description (Section 5.4.3: PWR power control/status register (PWR_CSR)).</p> <p><b>RCC:</b><br/>Updated Figure 20: Simplified diagram of the reset circuit and minimum reset pulse duration guaranteed by pulse generator restricted to internal reset sources.</p> <p><b>GPIOs:</b><br/>Updated Section 8.3.1: General-purpose I/O (GPIO).</p> <p><b>DMA:</b><br/>Updated direct mode description in Section 10.2: DMA main features.<br/>Updated direct mode description in Section : Memory-to-peripheral mode, and Section 10.3.12: FIFO/: Direct mode.<br/>Updated register access in Section 10.5: DMA registers.<br/>Modified Stream2 /Channel 2 in Table 42: DMA1 request mapping.<br/>Added note related to EN bit in Section 10.5.5: DMA stream x configuration register (DMA_SxCR) (x = 0..7). Updated definition of NDT[15:0] bits in Section 10.5.6: DMA stream x number of data register (DMA_SxNDTR) (x = 0..7).</p> <p><b>Interrupts:</b><br/>Updated number of maskable interrupts to 82 in Section 12.1.1: NVIC features.<br/>Updated Section 12.2: External interrupt/event controller (EXTI).</p> |

| Date        | Version | Changes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13-Nov-2012 | 3       | <p>Added STM32F42x and STM32F43x devices.</p> <p>Removed reference du Flash programming manual on cover page. Added Section 2.3.2: Flash memory overview and Section 3: Embedded Flash memory interface.</p> <p>Change RTC_50Hz into RTC_REFIN in Section 8.3.2: I/O pin multiplexer and mapping. Modified RTC alternate function naming in Section 8: General-purpose I/Os (GPIO) and Section 26: Real-time clock (RTC).</p> <p>Updated max. input frequency in Section 26.3.1: Clock and prescalers.</p> <p>Changed bit access type from 'rw' to 'w' and bit description updated in Section 10.5.3: DMA low interrupt flag clear register (DMA_LIFCR) and Section 10.5.4: DMA high interrupt flag clear register (DMA_HIFCR).</p> <p>Updated Figure 18: Frequency measurement with TIM5 in Input capture mode.</p> <p>Updated Section : Signals synchronization in Section 36: Flexible static memory controller (FSMC)</p> <p>Section 34: USB on-the-go full-speed (OTG_FS): updated Section Figure 389.: USB host-only connection, Section : VBUS valid, and Section : Host detection of a peripheral connection.</p> <p>Section 35: USB on-the-go high-speed (OTG_HS): updated Section : VBUS valid, and Section : Detection of peripheral connection by the host.</p>                                                                                                                                                    |
| 19-Feb-2013 | 4       | <p>Updated Section 2: Memory and bus architecture.</p> <p>Updated Figure 1: System architecture for STM32F405xx/07xx and STM32F415xx/17xx devices, and Figure 1: System architecture for STM32F405xx/07xx and STM32F415xx/17xx devices. Updated Table 4: Memory mapping vs. Boot mode/physical remap. Updated Figure 5: Sequential 32-bit instruction execution. removed note 1 from Table 13: Maximum program/erase parallelism.</p> <p><b>PWR:</b></p> <p>Updated Figure 7: Power supply overview.</p> <p>Updated Section 5.1.3: Voltage regulator.</p> <p>Added ADCDC1 bit in Section 5.5.1: PWR power control register (PWR_CR) for STM32F42xxx and STM32F43xxx.</p> <p><b>SYSCFG:</b></p> <p>Added ADCxDC2 bit in Section 8.2.3: SYSCFG peripheral mode configuration register (SYSCFG_PMC) for STM32F42xxx and STM32F43xxx.</p> <p><b>ADC:</b></p> <p>Updated Section 13.9.3: Interleaved mode, Section 13.9.4: Alternate trigger mode, and Section 13.9.5: Combined regular/injected simultaneous mode to describe case of interrupted conversion.</p> <p>Updated Section : Temperature sensor, VREFINT and VBAT internal channels, Section 13.10: Temperature sensor, and Section 13.11: Battery charge monitoring.</p> <p><b>RTC:</b></p> <p>Updated BKP[31:0] bit description in Section 26.6.20: RTC backup registers (RTC_BKPxR).</p> <p><b>I2C:</b></p> <p>Updated Section 27.3.5: Programmable noise filter.</p> |

|-------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15-Sep-2013 | 5       | <p>Added STM32F429xx and STM32F439xx part numbers.</p> <p>Replaced FSMC by FMC added Chrom-ART Accelerator, LCD-TFT and SAI interface.</p> <p>Updated Figure 2: System architecture for STM32F42xxx and STM32F43xxx devices.</p> <p><b>PWR:</b></p> <p>Updated Section 5.2.2: Brownout reset (BOR).</p> <p>Added note related to CSS enabling in Entering Stop mode sections in Section 5.3.4: Stop mode (STM32F405xx/07xx and STM32F415xx/17xx) and Section 5.3.5: Stop mode (STM32F42xxx and STM32F43xxx). Updated Stop mode entry in Table 27 and Table 29.</p> <p>Updated WUF bit definition in PWR_CSR registers. Changed CWUF and CSBF access type to 'w' in PWR_CR register.</p> <p><b>RCC:</b> Updated LSEBYP bit definition in RCC_BDCR register.</p> <p><b>GPIOs:</b></p> <p>Updated description of OSPEEDR bits. Removed frequency value in description of OSPEEDR bits. Corrected typos: "IDRy[15:0]" replaced with "IDRy" in "GPIOx_IDR" register, "ODRy[15:0]" replaced with "ODRy" in "GPIOx_ODR" register and "OTy[1:0]" replaced with "OTy" in "GPIOx_OTYPER" register.</p> <p><b>DCMI:</b> Updated Section 15.4: DCMI clocks.</p> <p><b>IWDG:</b> Corrected Figure 213: Independent watchdog block diagram.</p> <p><b>RTC:</b></p> <p>Replaced all occurrences of "power-on reset" with "backup domain reset". Added caution note under Table 121: RTC register map and reset values. Changed SHPF bit type to 'r' in Section 26.6.4: RTC initialization and status register (RTC_ISR)..</p> <p><b>SPI:</b> Updated definition of ERRIE bit in Section 28.5.2: SPI control register 2 (SPI_CR2).</p> <p><b>UART:</b></p> <p>Updated Section 30.3.8: LIN (local interconnection network) mode.</p> <p>Removed note in Section 30.3.13: Continuous communication using DMA.</p> <p><b>ETHERNET:</b></p> <p>Modified ETH_MACA0HR (and ETH_DMABMR reset values.</p> <p>Updated definitions of TSTS bit in ETH_MACSR, and TSTTR in ETH_PTPTSSR.</p> |
